CUMBERLAND PLAIN ASSESSMENT REPORT

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

How to navigate the Assessment Report

We recommend viewing the Cumberland Plain Assessment Report (the Assessment Report) using Adobe Acrobat Reader. To access and use Adobe Acrobat Reader follow the relevant steps of this process:

- Download and install Adobe Acrobat Reader by following this link https://get.adobe.com/reader/
- Download the report and save to your computer
- Right click on the report and select 'Open with Adobe Acrobat Reader'
- Click the bookmark symbol on the left side of the Adobe interface - the headings for each report Part will appear
- Click on the > symbol next to the Part headings - the headings for each report Chapter will appear

Navigate through the report by clicking on the Part and Chapter headings.

Contents of the Cumberland Plain Assessment Report

Supporting Document C - Expert reports

Supporting Document D - Trend analysis

Supporting Document E - Biodiversity credit report

Supporting Document F - SDM report

Supporting Document G - Implications of the 2019/20 bushfires

Supporting Document H – Department of Planning, Industry and Environment: response to submissions

Supporting Document I – Survey Report for the Green and Golden Bell Frog at Ropes Creek

Maps and figures used in the Assessment Report

The Assessment Report presents a range of maps. Maps are either presented as an A4 image within chapters of the document, or as a layered PDF file which is to be opened outside of the Assessment Report. Layered PDFs allow for the viewer to manipulate the visibility of data in the maps for ease of use.

The table below outlines the maps (both A4 images, and layered PDF) in the report. Note that the map or figure number is associated with the relevant chapter (for example, Map 3-1 is the first map in Chapter 3), and that A4 in text images are presented with a 'figure' number, while layered PDFs are presented with a 'map' number.

Chapter number	Map / Figure Number	Caption or file name	Format
PART 1: OVERVIEW			
1	Figure 1-1	Study area and location of Growth Areas and Transport Corridors	In text A4 image
2	Figure 2-1	Key steps in the regulatory processes	In text A4 image
3	Figure 3-1	Existing native vegetation within the study area	In text A4 image
4	N/A	N/A	N/A
PART 2: DESCRIPTION OF THE CUMBERLAND PLAIN CONSERVATION PLAN			
5	Figure 5-1	Program logic underpinning the Plan	In text A4 image
6	N/A	N/A	N/A
7	Figure 7-1	Wilton Growth Area and urban capable land	In text A4 image
	Figure 7-2	GMAC and urban capable land	In text A4 image
	Figure 7-3	WSA and urban capable land	In text A4 image
	Figure 7-4	GPEC and urban capable land	In text A4 image
	Figure 7-5	Agriculture and Agribusiness Precinct of WSA	In text A4 image
	Figure 7-6	Indicative locations of major transport corridors	In text A4 image
8	Figure 8-1	Location of Strategic Conservation Area	In text A4 image
	Figure 8-2	Key Koala movement corridors within the Plan Area	In text A4 image
9	Figure 9-1	Governance framework for the Plan	In text A4 image

Terms and acronyms used in the Cumberland Plain Assessment Report

Term	Acronym	Description
Accredited assessor		A BCAR can only be prepared by a person accredited under the accreditation scheme developed under Section 6.10 of the *Biodiversity Conservation Act 2016*.
Action		Activities that directly support the delivery of one or more commitments in the Plan. Actions may be amended using adaptive management throughout the life of the Plan.
Active restoration		When entering a Biodiversity Stewardship Agreement, a landholder can elect to undertake active restoration management actions which generate additional biodiversity credits. They include actions to restore or improve ecological features in a landscape, such as habitat enhancement, targeted supplementary planting to augment habitat and the control of high threat exotic vegetation. *See also required management actions*.
Adaptive management		A structured, iterative approach to help determine how management actions can be most effective in achieving the Plan's outcomes. It allows the implementation of the conservation program to respond to changing circumstances, and ensure the actions are delivering the commitments and meeting the outcomes.
Already protected land		Used to describe areas that are already protected from development for environmental reasons, including national parks, nature reserves, biodiversity stewardship sites and other protected lands.
Asset Protection Zone	APZ	A buffer zone between a bushfire hazard and buildings. It is managed to minimise fuel loads and reduce potential radiant heat levels, flames, localised smoke and ember attack. The appropriate APZ distance is based on vegetation type, slope and the nature of the development.
Avoided land		Land that has been avoided from development in the nominated areas through the conservation planning process undertaken as part of developing the Plan. This includes land: • Avoided for biodiversity. This is land that has high biodiversity values to be protected and that has been avoided from development within urban capable land • Avoided for other purposes. This is land that cannot be feasibly developed due to topography (area of steep slope within avoided lands) or is land that is mapped as a riparian corridor associated with a Strahler order 3 stream or above (or Strahler order 2 streams with mapped vegetation, adjacent to avoided lands or that contribute to landscape connectivity)
BioBanking agreements		Agreements administered under the repealed *Threatened Species Conservation Act 1995*. These agreements are now called Biodiversity Stewardship Agreements under the *Biodiversity Conservation Act 2016*.
BioBanking Assessment Method	BBAM	An assessment method made under the repealed *Threatened Species Conservation Act 1997* now replaced by the Biodiversity Assessment Methodology under the *Biodiversity Conservation Act 2016*.

Term	Acronym	Description
Biodiversity Assessment Method	BAM	An assessment method made under the *Biodiversity Conservation Act 2016* that is used to determine the impact of development and other activities on biodiversity values. The Biodiversity Assessment Method was used to prepare the BCAR component of this Assessment Report.
Biodiversity certification		A streamlined biodiversity assessment process for areas of land that are proposed for development provided for under the *Biodiversity Conservation Act 2016*. The process identifies areas that can be developed after they are certified and measures to offset the impacts of development. Where land is certified, development may proceed without the usual requirement for site by site assessment of biodiversity impacts.
Biodiversity Certification Assessment Report	BCAR	A report setting out the outcomes of an assessment of the impacts of a development on biodiversity values in accordance with the Biodiversity Assessment Method. It is required under the *Biodiversity Conservation Act 2016* and is submitted as part of an application for biodiversity certification.
Biodiversity Conservation Act 2016	BC Act	The primary biodiversity law in NSW. Establishes the Biodiversity Offset Scheme and provides for the biodiversity certification of land.
Biodiversity Conservation Regulation 2017	BC Regulation	Provides supporting regulatory detail under the *Biodiversity Conservation Act 2016.*
Biodiversity Conservation Trust	BCT	A statutory not-for-profit body established under Part 10 of the *Biodiversity Conservation Act 2016* to encourage and support landholders across NSW to participate in private land conservation.
Biodiversity Investment Opportunities Map	BIO Map	A map of core habitat areas and habitat corridors identified in western Sydney to guide investment in biodiversity conservation.
Biodiversity Offsets Scheme	BOS	A framework under the *Biodiversity Conservation Act 2016* to avoid, minimise and offset impacts on biodiversity from development and clearing, and to ensure land that is used to offset impacts is secured in-perpetuity with an appropriate level of funding to ensure management actions identified are implemented.
Biodiversity risk weighting	BRW	The Biodiversity Assessment Method uses a biodiversity risk weighting to evaluate the ecological risks of threatened entities from the biodiversity offsets scheme. The risk weighting is comprised of two components: • Sensitivity to loss – this considers the increased threat posed to an entity from offsetting the loss of habitat or population, and • Sensitivity to potential gain – this considers the ability of a species to respond to improvements in habitat condition at an offset site
Biodiversity Stewardship Agreement	BSA	A voluntary agreement between a landholder and the Biodiversity Conservation Trust to permanently protect and manage an area of their land to improve its biodiversity values. It enables landholders to generate an income through trading biodiversity credits. Credits are generated by the expected improvement in biodiversity under management at the site.

Term	Acronym	Description
Biodiversity values		Biodiversity values are defined in the *Biodiversity Conservation Act 2016* as including: *(a) vegetation integrity—being the degree to which the composition, structure and function of vegetation at a particular site and the surrounding landscape has been altered from a near natural state* *(b) habitat suitability—being the degree to which the habitat needs of threatened species are present at a particular site* Impacts of the development on biodiversity values are required to be considered under the Biodiversity Assessment Method
Biodiversity Values Map		The Biodiversity Values Map identifies land with high biodiversity value that is particularly sensitive to impacts from development and clearing. The map forms part of the Biodiversity Offsets Scheme Threshold which is one of the triggers for determining whether the Biodiversity Offset Scheme applies to a clearing or development proposal.
BioNet Atlas		NSW database managed by EES containing data on species records.
BioNet Vegetation Classification		NSW database managed by EES containing data on Plant Community Types. *See also Plant Community Types.*
Candidate species		A Species Credit Species requiring assessment in the BCAR under the Biodiversity Assessment Method
Category 1 matters		Matters protected under the *Environment Protection and Biodiversity Conservation Act 1999* that need detailed assessment in the Strategic Assessment Report. These matters are reliant on the Strategic Assessment Area, have some potential to be impacted (directly, indirectly or cumulatively), and are addressed in detail in this report.
Category 2 matters		Matters protected under the *Environment Protection and Biodiversity Conservation Act 1999* that do not need further assessment in the Strategic Assessment Report. These matters are not reliant on the Strategic Assessment Area, are subject to no or very low risk of impacts (directly, indirectly or cumulatively), and are not addressed further in this report.
Certified – urban capable land		Land identified for future urban and industrial development, infrastructure, and intensive plant agriculture within the nominated areas that is proposed for biodiversity certification under the *Biodiversity Conservation Act 2016* and strategic approval under the *Environment Protection and Biodiversity Conservation Act 1999.* This category of land identifies where future development is likely to occur, subject to other approvals. Also referred to as urban capable land in this Assessment Report
Class of action approval		Class of actions describe the projects covered by the approval that do not need individual referral, assessment or approval under the *Environment Protection and Biodiversity Conservation Act 1999* provided they are undertaken in accordance with the endorsed final strategic assessment. Classes of actions covered under the Plan are: • Urban and industrial development • Infrastructure • Intensive plant agriculture • Major transport corridors These are referred to as 'development types' in the Assessment Report

Term	Acronym	Description
Commonwealth Government Department of Agriculture, Water and the Environment	DAWE	The Commonwealth Government department primarily responsible for environment protection and conservation at a national level.
Commitment		A defined milestone under the Plan which will be met through the delivery of the actions. *See also Action*
Connectivity		Areas that connect different areas of habitat, facilitating movement of threatened and more common species across their distribution. The presence of connectivity on a site contributes to the biodiversity value of that site at the landscape scale. Connectivity can be identified at different scales depending on the target species and can include broad biodiversity corridors, a local corridor identified by a council, flyways for migratory species or a riparian corridor of a stream, wetland or estuary.
Conservation lands		Conservation lands are sites of high biodiversity value identified for protection under the Plan to offset the residual impacts of the development on biodiversity values. Conservation lands include locations where ecological restoration may also occur.
Conservation Priorities Method		A systematic and repeatable method developed as part of the Plan for determining and prioritising new conservation lands. The method was used to determine the Strategic Conservation Area.
Conservation program		A package of commitments and actions to offset the residual impacts of the development under the Plan on biodiversity values and to ensure that the Plan's outcomes are delivered.
Cumberland Interim Biogeographic Regionalisation for Australia subregion (or 'Cumberland subregion')	IBRA subregion	Developed by the Commonwealth Government as a key planning tool to identify land for conservation. It has since become a spatial mapping and information source on vegetation communities and ecosystems across Australia. The Cumberland IBRA subregion is the main focus of this Plan, with most of the Plan Area occurring within this subregion.
Cumberland Plain		A relatively flat, broad geographic basin located within the Cumberland IBRA subregion in the Sydney region, identified by dominant older shale and younger alluvial geology.
Cumberland Plain Assessment Report	Assessment Report	Refers to this report. The Assessment Report assesses the potential impacts of the proposed development under the Plan on biodiversity values and other matters regulated under the NSW and Commonwealth biodiversity laws. The report is a single report prepared to meet the statutory requirements for both: • A Biodiversity Certification Assessment Report prepared in accordance with the Biodiversity Assessment Method under the *Biodiversity Conservation Act 2016* • A Strategic Assessment Report prepared in accordance with the Terms of Reference provided under the Part 10 Strategic Assessment Section 146 Agreement between the Commonwealth Minister for the Environment and the State of NSW under the *Environment Protection and Biodiversity Conservation Act 1999*

Term	Acronym	Description
Cumberland Plain Conservation Plan	Plan	The subject of this report. The Plan is a strategic conservation plan developed to manage and offset the impacts on biodiversity from projected growth in Western Sydney. The Plan will deliver a conservation program to protect and enhance biodiversity at a landscape scale while balancing the future needs of the local community.
Cumulative impacts		Cumulative impacts are the combined impact of past, present and future human activities and natural processes.
Derived native grasslands	DNG	Derived native grassland is a native grassland remaining after the removal or dieback of previous woody canopy vegetation (shrubs or trees), to a point where woody vegetation has less than 10 per cent cover.
Development Control Plan	DCP	Provides detailed planning and design guidelines to support the planning controls in a Local Environmental Plan or State Environmental Planning Policy.
Digital Elevation Model	DEM	A gridded layer of elevation that represents a terrain's surface.
District Plan		An integrated land use, transport and infrastructure plan outlining the local priorities and actions for implementing the *Greater Sydney Region Plan, A Plan for Growing Sydney*. There are five District Plans for the Western City, Central City, Eastern City, North and South districts.
Ecological function		Ecological function is the potential of an ecosystem to deliver a service that is dependent on ecological processes and structures. It considers how species interact with and affect their environment and involves any process that can cause change or may be changed by external influences.
Ecological restoration		Ecological restoration is the process of assisting the recovery of an ecosystem that has been degraded, damaged or destroyed through actively managing restoration. It is also sometimes called rehabilitation or revegetation. *See also Reconstruction.*
Ecological Sustainable Development	ESD	Defined as using, conserving and enhancing the community's resources so that ecological processes, on which life depends, are maintained, and the total quality of life, now and in the future, can be increased. Additional definitions can be found under Section 6 of the *Protection of the Environment Administration Act 1991* and Section 3A of the *Environment Protection and Biodiversity Conservation Act 1999.*
Ecosystem Credit Species	ECS	A category of species defined under the Biodiversity Assessment Method.
Environment Protection and Biodiversity Conservation Act 1999 (Cth)	EPBC Act	The Commonwealth Government's central piece of environmental legislation, which provides a framework to protect and manage Matters of National Environmental Significance.
Environmental Planning and Assessment Act 1979 (NSW)	EP&A Act	The primary planning legislation in NSW. Provides a legal framework for land use planning, how land is to be developed and managed and the creation of environmental plans. It is administered by the NSW Department of Planning, Industry and Environment.
Environmental Planning Instruments	EPI	The collective name for Local Environmental Plans and State Environmental Planning Policies.

Term	Acronym	Description
Excluded land		Land which has been excluded from the Plan and for which NSW strategic biodiversity certification and approval through the Commonwealth strategic assessment will not be sought. These lands include: • Existing protected land, including reserves and established offset sites • Commonwealth land, such as Orchard Hills Defence Establishment • Lands already assessed as part of another development approval (Bingara Gorge), lands progressing through an alternate development assessment (Mount Gilead and Menangle Park) • Lands already developed (existing urban areas and urban land zones)
Existing North West and South West Growth Areas		The new term for the North West and South West Growth Centres.
Extent of occurrence	EOO	The area contained within the shortest continuous imaginary boundary which can be drawn to encompass all known, inferred or projected sites of present occurrence of a species or ecological community, excluding cases well outside an entity's normal distribution.
Facilitated impacts		Impacts that result from further actions (including actions by third parties) which are made possible or facilitated by the action.
Finalised priority assessment list	FPAL	List of species, ecological communities, and key threatening processes that have been nominated and approved for assessment and consideration for listing by the Minister responsible for the *Environment Protection and Biodiversity Conservation Act 1999*.
Future Transport Strategy 2056		The Future Transport Strategy is a 40-year strategy which will guide NSW transport investment over the longer term. It is an update of the 2012 Long Term Transport Master Plan for NSW.
Greater Macarthur Growth Area	GMAC	One of the four nominated areas the NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.
Greater Penrith to Eastern Creek Investigation Area	GPEC	One of the four nominated areas that NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.
Greater Sydney Commission	GSC	A NSW Government agency leading strategic metropolitan planning for the Greater Sydney region. Their strategic plans serve to make Greater Sydney more productive, liveable and sustainable for future generations.
Greater Sydney Region Plan		A 20-year integrated land use, transport and infrastructure plan outlining the priorities and actions for Greater Sydney.
Important Koala habitat		The term used to describe primary, secondary and tertiary movement corridors for Koala. It is the area that is critical to the long-term viability of koalas (primary corridors) as well as the areas (if enhanced) that would support the population (secondary and tertiary corridors). *See also Koala movement corridors*

Term	Acronym	Description
Important population		Important populations are defined in the Commonwealth's *Significant Impact Guidelines (Policy Statement 1.1)* as: "*Any population of a vulnerable species which meets the definition of an important population in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) as follows:* *'A population that is necessary for a species' long-term survival and recovery. This may include populations identified as such in recovery plans, and/or that are:* • *key source populations either for breeding or dispersal* • *populations that are necessary for maintaining genetic diversity, and/or* • *populations that are near the limit of the species range*" For the purposes of the SAR, important populations are also defined as including any population of an endangered or critically endangered species. Under the *Environment Protection and Biodiversity Conservation Act 1999*, all populations of an endangered or critically endangered species are considered to be important for the survival and recovery of the species.
Indirect impacts		Include downstream, downwind, upstream and facilitated impacts (e.g. fertilisers washed into river systems, extraction of raw materials, and construction of a dam facilitates water use).
Knowledge Based Method	KBM	Method used to map species habitat within the nominated areas, including species polygons under the Biodiversity Assessment Method, where expert reports were not prepared. Method was based on assumed presence within relevant Plant Community Types, which was refined where appropriate based on habitat or geographic constraints and species surveys.
Koala movement corridors		Koala movement corridors are areas of habitat (often but not always linear) which facilitate the movement and dispersal of koalas between habitat patches which would otherwise be disconnected. Koala movement corridors facilitate Koala population dispersal, which protects against localised extinctions, as Koalas require large, connected areas of important habitat for feeding and breeding.
Land Category		The Plan categorises land within the nominated areas into: • Certified – urban capable land • Certified – major transport corridor • Excluded land • Avoided land • Major transport corridor (strategically assessed only) • Major transport corridor tunnel (strategically assessed only)
Land Use and Infrastructure Implementation Plan	LUIIP	A strategic plan that provides an overview of future land uses and the proposed sequence of development to ensure new jobs and homes are delivered in alignment with infrastructure.
Local Aboriginal Land Council	LALC	An autonomous body which is governed by Boards elected by local Aboriginal community members every two years. LALCs were established under the Aboriginal Land Rights Act 1983 as the elected representatives for Aboriginal people in NSW. The Plan Area includes three LALCs: Deerubbin, Tharawal and Gandangara.
Local Environmental Plan	LEP	An environment planning instrument that guides planning and development decisions within a local government area in NSW. This is achieved through zoning and development controls, which provide a framework for the way land can be used.

Term	Acronym	Description

Major transport corridors		The major transport corridors are part of the NSW Government's planning for the long-term transport needs of Western Sydney by identifying and protecting corridors of land that can be used to deliver road and rail infrastructure when needed in the future. The transport infrastructure will be constructed and delivered to 2056. The major transport corridors are subject to different statutory approvals under the Plan and are categorised in the Assessment Report to reflect this:
		• Major transport corridors within the nominated areas are subject to biodiversity certification under the *Biodiversity Conservation Act 2016* and approval under Part 10 of the *Environment Protection and Biodiversity Conservation Act 1999*. These are referred to as: Certified - major transport corridor
		• Major transport corridors outside the nominated areas are subject to approval under Part 10 of the *Environment Protection and Biodiversity Conservation Act 1999* only. These are referred to as:
		  o Major transport corridor (strategically assessed only)
		  o Major transport corridor tunnel (strategically assessed only)
		Note that a small part of the tunnel section of the major transport corridors occurs within a nominated area (GMAC), but this is not subject to biodiversity certification under the *Biodiversity Conservation Act 2016*

Management action		An action under a Biodiversity Stewardship Agreement required to improve the condition of native vegetation or species habitat. These could include activities such as native vegetation management (restoring native vegetation, retaining and managing regrowth, nutrient control), pest animal control, weed management, among others.
Matters of National Environmental Significance	MNES	Defined under the *Environment Protection and Biodiversity Conservation Act 1999* as: • Listed threatened species and communities • Migratory species • Wetlands of international importance (listed under Ramsar) • Commonwealth marine environment • World Heritage properties • National Heritage places • The Great Barrier Reef Marine Park • Nuclear actions • A water resource, in relation to coal seam gas development and large coal mining development
Monitoring, Evaluation and Reporting	MER	The process of tracking and reviewing projects over time to ensure outcomes are met. For the Plan, this term is referred to as the 'evaluation program' and will provide assurance that Plan's outcomes and commitments are being satisfied and clarity for delivery partners on how to appropriately measure and report in a coordinated manner.
Native vegetation		Native vegetation is any plant native to NSW prior to European settlement, defined in Part 5A of the *Local Land Services Act 2013*. It can also include any plant, living or dead, in mapped Category 2-vulnerable land and generally excludes marine vegetation. Native vegetation species when occurring together form native vegetation communities, which in NSW are called Plant Community Types. *See also Plant Community Types*

Term	Acronym	Description
Nominated area		A nominated area is an area in Western Sydney identified for future growth which seek approvals through the Plan under the *Biodiversity Conservation Act 2016* and *Environment Protection and Biodiversity Conservation Act 1999*. These areas include: • Wilton Growth Area • Greater Macarthur Growth Area • Western Sydney Aerotropolis • Greater Penrith to Eastern Creek Investigation Area
Non-offsettable grassland	NoG	Comprises grassland vegetation zones with a vegetation integrity score of <15 and does not require offsetting for the associated Plant Community Type under the Biodiversity Conservation Method.
NSW (Mitchell) Landscapes		Mitchell Landscapes were mapped in 2002 using a combination of landsystems in the west of NSW and geology and Digital Elevation Model (DEM) in the east of NSW. There have been a number of new versions since the original mapping. The most recent is version 3.1.
NSW Environment Energy and Science	EES	The NSW Government department responsible for environment protection and conservation of biodiversity amongst other things. Formerly known as Office of Environment and Heritage (OEH).
NSW Government Department of Planning, Industry and Environment	The Department	The NSW Government department responsible for effective and sustainable planning and the development of industry to support growth.
NSW Koala Strategy		Identifies a set of short-term actions as part of a longer-term goal to stabilise and increase koala populations in NSW.
NSW Office of Environment and Heritage	OEH	A former office of the NSW Government from 2011 to 2019. Now known as NSW Environment Energy and Science.
Office of the NSW Chief Scientist & Engineer.		An office of the NSW Government with four key functions: • Independent Advice to government on scientific issues • Research Support – the office manages the NSW Government's Research Attraction and Acceleration Program • Industry Development – the office brings academia, government and industry together to drive the commercialisation of research excellence • Science Outreach and Education – the office is committed to ensuring that both students and the general public are given the opportunity to engage with science and scientists
Offset location		An 'offset location' is a site where one or more populations and habitat of the species has been confirmed through surveys or an expert report as being present. Offset location sites may be reserves or BSA sites. For a biodiversity stewardship site, this means credits representing a reasonable proportion of habitat and/or number of individuals of a local population of the threatened species are purchased and retired against the Plan's offset targets.
Outcome		An outcome is a reported or measurable result of a desired goal. In the Plan, it is the intended environmental, economic or social impact or value of delivering the Plan's commitments.

Term	Acronym	Description
Outer Sydney Orbital	OSO	Outer Sydney Orbital (Stage 1) from Palmyra Avenue to the Hume Motorway and remaining Outer Sydney Orbital 1 provides for a future north south motorway and freight rail line.
Plan Area		The area covered by the Cumberland Plain Conservation Plan, which covers around 200,000 hectares and includes the Cumberland IBRA subregion and some minor areas of the adjacent Sydney Cataract and Wollemi IBRA subregions. It extends from 10 kilometres north of Windsor to Picton in the south, and from the Hawkesbury-Nepean River in the west to east near Liverpool. It includes sections of eight Local Government Areas – Wollondilly, Camden, Campbelltown, Liverpool, Fairfield, Penrith, Blacktown and Hawkesbury.
Plant Community Type	PCT	The community-level grouping used in NSW's planning and assessment tools and vegetation mapping programs. They are identified in the BioNet Vegetation Classification (VIS) database.
Precinct planning		Ensures that nominated areas are strategically planned and infrastructure is delivered in a coordinated manner. The program identifies the development intent and development capacity across an entire precinct, through the allocation of housing choices, built form, infrastructure, and environmental and open space desires.
Prescribed impact		Prescribed impacts are impacts on biodiversity values which are not related to, or are in addition to, native vegetation clearing and habitat loss. Prescribed impacts are required to be assessed under the Biodiversity Assessment Method.
Primary corridors		Movement corridors for Koala that are defined as 'connected areas of Koala habitat that are contiguous (gaps between trees less than 100 metres) and together contain greater than 380 ha of Koala habitat'.
Protected Koala habitat		Koala habitat that has been included in the Plan's strategic conservation area and/or the avoided land. It includes some areas of cleared land that may be restored to enhance koala corridors and habitat.
Protected matters search tool	PMST	A database that identifies whether MNES or other matters protected by the *Environment Protection and Biodiversity Conservation Act 1999* are likely to occur within an area or vicinity.
Ramsar Wetlands		A list of Wetlands of International Importance identified in the Ramsar Convention, which is maintained by the Commonwealth.
Reconstruction		An ecological restoration approach where the appropriate biota needs to be entirely or almost entirely reintroduced as they cannot regenerate or recolonise within feasible timeframes, even after expert assisted regeneration interventions. *See also Ecological restoration*
Reserves		Reserves are conservation lands of high biodiversity value typically managed by NSW National Parks and Wildlife Services or councils. Reserves can include national parks, nature reserves, regional parks, council reserves and community reserves.

Term	Acronym	Description
Riparian		Riparian refers to lands that relate to waterways and parts of the landscape influenced by streams and flowing fresh water. The riparian buffer is defined in the Biodiversity Assessment Method as being within a certain distance from the top of the bank of a waterway of particular order.
Saving Our Species program	SOS	The Saving Our Species program is an initiative in which the NSW Government is investing $100 million over five years (from 2016 to 2021) to protect threatened species from extinction.
Secondary corridors		Movement corridors for Koala that are defined as: 'smaller movement corridors that either have 'pinch points' which become narrow to less 50 metres wide, or that are not connected at both ends to other koala habitat'.
State Environmental Planning Policy	SEPP	An environmental planning instrument that deals with matters of State or regional environmental planning significance.
Serious and irreversible impacts	SAII	A determination of whether an impact is serious and irreversible is made in accordance with the principles prescribed in section 6.7 of the *Biodiversity Conservation Regulation 2017*. Threatened species and ecological communities will be at risk of serious and irreversible impacts if they are in a rapid rate of decline, have a very small population size, are severely degraded or disrupted, have a very limited geographic distribution or are unlikely to respond to measures to improve habitat.
Special Infrastructure Contribution		Levy contributions from developers to fund the delivery of State and regional infrastructure required to support a growing population, such as roads, public transport, health facilities, emergency services, schools, and open space and provide for biodiversity management.
Species Credit Species	SCS	A category of species defined under the Biodiversity Assessment Method
Species Distribution Model	SDM	Statistical models used to estimate the relationship between species records at sites and the environmental and/or spatial characteristics of those sites. Once this relationship has been estimated, the SDM can be used to predict other locations in the landscape where the species is likely to occur. Species Distribution Modelling was undertaken for Commonwealth listed Category 1 species mainly outside the nominated areas, where adequate species records were available to develop a model.
Strategic assessment		Landscape-scale assessments undertaken under Part 10 of the *Environment Protection and Biodiversity Conservation Act 1999*. Unlike project-by-project assessments, which look at individual actions, strategic assessments can consider a much broader set of actions over a much larger scale and timeframe, such as a plan, policy or program.
Strategic Assessment Agreement		The formal agreement between the Commonwealth Minister for Environment and the State of NSW to enter into the Strategic Assessment for the Cumberland Plain Conservation Plan. It is a mandatory requirement under the *Environment Protection and Biodiversity Conservation Act 1999*, and formally establishes the expectations of both parties.
Strategic Assessment Area		The area subject to assessment of impacts on biodiversity values in the Strategic Assessment Report under the *Environment Protection and Biodiversity Conservation Act 1999*. The Assessment Report defines the assessment area for the Strategic Assessment Report as the Plan Area.
Strategic Assessment Report	SAR	An assessment report done in accordance with the Terms of Reference for the strategic assessment provided under the Strategic Assessment Agreement. *See also Strategic Assessment Agreement.*

Term	Acronym	Description
Strategic biodiversity certification		A form of biodiversity certification available only to planning authorities such as the Department of Planning and Environment, to support significant regional development and planning processes.
Strategic Conservation Area	SCA	An area of high biodiversity value determined using the Conservation Priorities Method. It contains large remnants of native vegetation with good connectivity, or areas with the potential to enhance connectivity in the Plan Area. The Strategic Conservation Area will be used to identify potential conservation lands for further investigation.
Strategic Conservation Planning		A landscape-scale approach to assessing and protecting biodiversity upfront in planning for large-scale development. Allows for streamlined delivery of housing and infrastructure while protecting regionally important land for conservation and publicly accessible green space.
Strategic Environmental Assessment	SEA	Prepared as part of the process of identification and protection of the major transport corridors that provides for an assessment of the environmental, economic and social impacts of reserving the corridor. SEAs are non-statutory documents that assist in planning and decision making. They are subject to public consultation and include justification for a preferred corridor alignment and provide information on the assessment of alternative corridor alignments.
Structured decision-making		The Department applied a structured decision-making process during early development of the Plan to define a high-level biodiversity outcome for the Cumberland subregion that set the context and direction for the development of the Plan. The process was one of the first steps in a comprehensive conservation planning process for the Plan.
Structure Plan		A strategic plan providing a spatial representation of high-level land uses, environmental assets and transport infrastructure within a nominated area. It includes overarching planning principles, distribution of land uses, the phasing of precincts and identification of a high-level transport framework, the Blue–Green Grid and other key infrastructure.
Sub-Plan A		Sub-Plan A of the Cumberland Plain Conservation Plan: Conservation Program and Implementation
Sub-Plan B		Sub-Plan B of the Cumberland Plain Conservation Plan: Koalas
Subject Land		The area subject to assessment of impacts on biodiversity values in the Biodiversity Certification Assessment Report under the Biodiversity Assessment Method. The Assessment Report defines the assessment area for the Biodiversity Certification Assessment Report as the nominated areas.
Terms of Reference	ToR	Terms of Reference are a requirement under the *Environment Protection and Biodiversity Conservation Act 1999* for undertaking a strategic assessment and are prepared in accordance with the Strategic Assessment Agreement. The Terms of Reference outline the requirements for the Strategic Assessment Report, including how impacts to matters of national environmental significance should be assessed and how outcomes of the Plan are evaluated.
Tertiary corridors		Movement corridors for Koala that are defined as: 'smaller corridor areas that are not connected at the landscape level'

Term	Acronym	Description
Threatened Biodiversity Data Collection	TBDC	A database maintained in the NSW BioNet Atlas consisting of profiles for threatened species, populations and ecological communities that occur in NSW and used as part of the Biodiversity Assessment Method.
Threatened Ecological Community	TEC	An ecological community may be listed as vulnerable, endangered or critically endangered under the *Biodiversity Conservation Act 2016* and/or *Environment Protection and Biodiversity Conservation Act 1999* depending on the level of threat and risk of its collapse.
Urban capable land		Land identified for future urban and industrial development, infrastructure, and intensive plant agriculture within the nominated areas that is proposed for biodiversity certification under the *Biodiversity Conservation Act 2016* and strategic approval under the *Environment Protection and Biodiversity Conservation Act 1999*. This category of land identifies where future development is likely to occur, subject to other approvals. Also referred to as certified land in this Assessment Report
Vegetation integrity score	VI score	A measure of vegetation condition used under the Biodiversity Assessment Method. Represents a combination of different scores for vegetation composition, structure and function.
Vegetation zones		A vegetation zone is an area of native vegetation that is the same Plant Community Type and has a similar broad condition state.
Western City District Plan		The Western City District Plan provides a 20-year plan to manage growth and achieve liveability, productivity and sustainability into the future for Western Sydney. It is one of the Greater Sydney Commission's five district plans and provides a link between local and regional planning
Western Sydney		A major region of Sydney comprised of 12 local government areas: Blacktown, Canterbury-Bankstown, Camden, Campbelltown, Cumberland, Fairfield, Hawkesbury, Liverpool, Parramatta, Penrith and Wollondilly.
Western Sydney Aerotropolis	WSA	One of the four nominated areas that the NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.
Western Sydney City Deal		The City Deal is a 20-year agreement to deliver a transformation of Sydney's outer west. The Commonwealth and NSW Governments, together with eight local governments of Western Sydney, signed the Western Sydney City Deal on 4 March 2018.
Wilton Growth Area	Wilton	One of the four nominated areas that the NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.
Working group		Working groups will be established under the Plan to determine priorities and support delivery of the Plan's commitments to meet outcomes for a specific area of focus. They will comprise relevant stakeholders and experts as required. Three working groups are proposed to be established under the Plan: compliance, koalas, and pest and animal control.

CUMBERLAND PLAIN ASSESSMENT REPORT

PART 1: OVERVIEW

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

DOCUMENT TRACKING

PREPARED BY:	
DATA:	N/A
CONTENT:	Tom Holden, Peter Hemphill, Heather Tolley, Natasha Buckingham, Mitchell Ross, Stephanie Binks, Heidi Birkby, Christa Shen (Open Lines)
REVIEWED BY:	
OPEN LINES:	Peter Hemphill (Open Lines)
ACCREDITED ASSESSOR:	Jane Raithby-Veall (Biosis) BAM Assessor (BAAS18134)
VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 1 Contents

Part 1 List of Figures

Part 1 List of Tables

1 Introduction

The NSW Government has identified four areas for urban growth and other development ('nominated areas') and a series of major transport corridors within and outside the nominated areas to support the future growth of Western Sydney until 2056. These initiatives are identified under two key planning strategies:

- *A Metropolis of Three Cities - The Greater Sydney Region Plan* (GSC, 2017)
- *Future Transport 2056* (Transport for NSW, 2018)

The nominated areas program represents the strategic prioritisation and delivery of new development as part of the long-term growth of Greater Sydney provided under the Greater Sydney Region Plan. The nominated areas are the key focus for development until 2056 and will be the centres of economic activity in Western Sydney.

The major transport corridors are part of the NSW Government's planning for the long-term transport needs of Western Sydney by identifying and protecting corridors of land that can be used to deliver road and rail infrastructure when needed in the future. The transport infrastructure will be constructed and delivered over the next few decades.

The nominated areas program is administered by the NSW Department of Planning, Industry and Environment (the Department). The major transport corridors program is administered by Transport for NSW.

The Department is progressing the approvals required for the development. As part of the biodiversity approvals required, the Department is preparing the Cumberland Plain Conservation Plan (the Plan) to provide long-term certainty for biodiversity and development in Western Sydney. The Plan sets out:

- Proposed development under the Plan
- A conservation program to achieve the Plan's objective and outcomes and offset the impacts of development on biodiversity values
- How the Plan will be implemented

The Plan will support two separate statutory approvals processes under State and Commonwealth laws required to address the impacts of the proposed development on biodiversity values, in accordance with:

- Strategic biodiversity certification under Part 8 of the *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment under Part 10 of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act)

This Cumberland Plain Assessment Report (Assessment Report) assesses the potential impacts of the proposed development under the Plan on biodiversity values regulated under the BC Act and EPBC Act.

The strategic biodiversity certification and strategic assessment processes aim to reduce the costs and timeframes associated with regulation of the proposed development under the two Acts, and more effectively manage the biodiversity impacts of planned growth and improve biodiversity outcomes in the long term by:

- Removing duplication between NSW and Commonwealth biodiversity laws
- Replacing site by site assessments and approvals for individual projects that would generally be needed under both the BC Act and EPBC Act for the proposed development with a single and strategic approval approach

1.1 DESCRIPTION OF THE PLAN

The Plan supports the delivery of infrastructure, housing and jobs for Western Sydney in a planned and strategic way that also protects and maintains key biodiversity values of the Cumberland Plain.

The Plan includes a conservation program of commitments and actions that seeks to improve ecological resilience and protect biodiversity in the Cumberland Plain and provide an enduring conservation legacy for Western Sydney.

The Plan comprises an overall Plan and two Sub-Plans. These documents cover three key elements:

- Development – this covers the urban and industrial, infrastructure, intensive plant agriculture, and major transport corridors under the Plan, including the scope and location of the development

- Conservation – this covers the conservation program and a set of commitments to achieve the Plan's objective and to offset the impacts of the development on biodiversity values
- Implementation framework – this covers how the Plan will be implemented

The Plan is described in detail in Part 2.

1.2 PLAN TIMING

The Plan will be implemented over the period to 2056 and the Department is seeking that the approvals for the Plan have effect until this date. This timing aligns with implementation of the *Greater Sydney Region Plan: A Metropolis of Three Cities* (GSC, 2018) and the *Future Transport Strategy 2056* (Transport for NSW, 2018).

1.3 THE PLAN AREA

The Plan Area is shown in Figure 1-1.

The Plan Area is primarily within the Interim Biogeographic Regionalisation for Australia (IBRA) Cumberland subregion of the Sydney Basin Bioregion. It also includes some minor areas of the adjacent Sydney Cataract and Wollemi subregions. The area covered is approximately 200,000 hectares (see Figure 1-1).

The Cumberland subregion is a broad geographic feature bounded by the elevated lands of the Hornsby Plateau in the north, the base of the Blue Mountains to the west, the Woronora plateau in the south, and the Sydney CBD to the east.

The Plan Area for this project lies generally within the Western part of the subregion and extends from about 10 km north of Windsor south to Tahmoor (south of Picton), and from approximately Silverdale eastwards to Liverpool, and includes all or part of eight Local Government Areas (LGAs), being:

- Camden Council
- City of Blacktown
- City of Campbelltown
- City of Fairfield
- City of Hawkesbury
- City of Liverpool
- City of Penrith
- Wollondilly Shire

1.4 PURPOSE OF THIS REPORT

The Assessment Report assesses the potential impacts of the proposed development under the Plan on biodiversity values and other matters regulated under the BC Act and EPBC Act. The Assessment Report is a single report prepared to meet the statutory requirements for both:

- A Biodiversity Certification Assessment Report (BCAR) prepared in accordance with the Biodiversity Assessment Method (BAM) made under the BC Act
- A Strategic Assessment Report (SAR) prepared in accordance with the Terms of Reference (ToR) for the SAR provided under the Part 10 Strategic Assessment Section 146 Agreement between the Commonwealth Minister for the Environment and the State of NSW under the EPBC Act (see Supporting Document A)

1.4.1 ASSESSMENT AREAS FOR THE BCAR AND SAR

The assessment areas differ for the BCAR and SAR components of the Assessment Report:

- For the BCAR, the assessment area is called the Subject Land and covers the nominated areas
- For the SAR, the assessment area is called the Strategic Assessment Area and covers the area of the Plan

1.4.2 PURPOSE OF BCAR COMPONENT OF THE REPORT

The purpose of the BCAR component of this Assessment Report is to provide an assessment of the proposed development taken under the Plan in accordance with stages 1 and 2 of the BAM, including:

- Identifying and assessing the biodiversity values of the area covered by the proposed development
- Quantifying the impacts on biodiversity values of the proposed development
- Describing the commitments and actions to offset the impacts of the development, including the number and classes of biodiversity credits that would be required to be retired if the offset rules under the Biodiversity Conservation Regulation 2017 (BC Regulation) applied

As the proposed development has been determined by the NSW Environment Minister to be considered for approval under a 'strategic biodiversity certification', the offset rules under the BC Regulation do not apply and the Minister can determine any measure to be a conservation measure (see Section 2.1).

The BCAR component of this Assessment Report will be considered by the NSW Minister for the Environment in deciding to confer strategic biodiversity certification for the proposed development under the BC Act.

1.4.3 PURPOSE OF SAR COMPONENT OF THE REPORT

The purpose of the SAR component of this Assessment Report is to address the ToR and assess the impacts of the proposed development taken under the Plan on all matters protected by Part 3 of the EPBC Act (protected matters).

The SAR component of this Assessment Report will be considered by the Commonwealth Environment Minister in deciding to endorse the Plan under the EPBC Act. If the Plan is endorsed by the Minister, the Minister may subsequently consider approval of the proposed development in accordance with the endorsed Plan.

1.5 SCOPE OF THE DEVELOPMENT

The scope of the proposed development broadly comprises:

- Urban and industrial development within urban capable land in the nominated areas
- Infrastructure within urban capable land in the nominated areas, as well as 'essential' infrastructure in limited cases within avoided lands in the nominated areas
- Intensive plant agriculture within the Agribusiness Precinct in the Western Sydney Aerotropolis (WSA)
- Major transport corridors within and outside the nominated areas

Figure 1-1 shows the location of the four nominated areas and the major transport corridors.

The nominated areas comprise:

- Greater Macarthur Growth Area (GMAC)
- Greater Penrith to Eastern Creek Investigation Area (GPEC)
- Western Sydney Aerotropolis (WSA) (excluding where there is overlap with the existing South West Growth Area)
- Wilton Growth Area (Wilton)

The major transport corridors comprise major road or rail projects within identified corridors. The corridors are located within three of the nominated areas – GPEC, WSA and GMAC (but not Wilton) as well as outside the nominated areas. Parts of some of the corridors comprise sections of tunnels, where disturbance to the land surface will be minimised.

As described in Section 1.6, the major transport corridors are subject to different statutory approvals under the Plan and are categorised in this Assessment Report to reflect this:

- Major transport corridors within the nominated areas are subject to biodiversity certification under the BC Act and approval under Part 10 of the EPBC Act. These are referred to as 'Major transport corridors (certified)'
- Major transport corridors outside the nominated areas are subject to approval under Part 10 of the EPBC Act only. These are referred to as:
    - 'Major transport corridors – non-certified (strategically assessed)'

- ‘Major transport corridors tunnel – non-certified (strategically assessed)’

Note that a small part of the tunnel section of the major transport corridors occurs within a nominated area (GMAC), but this is not subject to biodiversity certification under the BC Act

Not all parts of the nominated areas are proposed for development. The proposed development will occur within specified urban capable lands within each nominated area. These are shown in Figure 1-1.

Further details of the proposed development, including the different major transport corridors and their approval category under the Plan, are provided in Part 2.

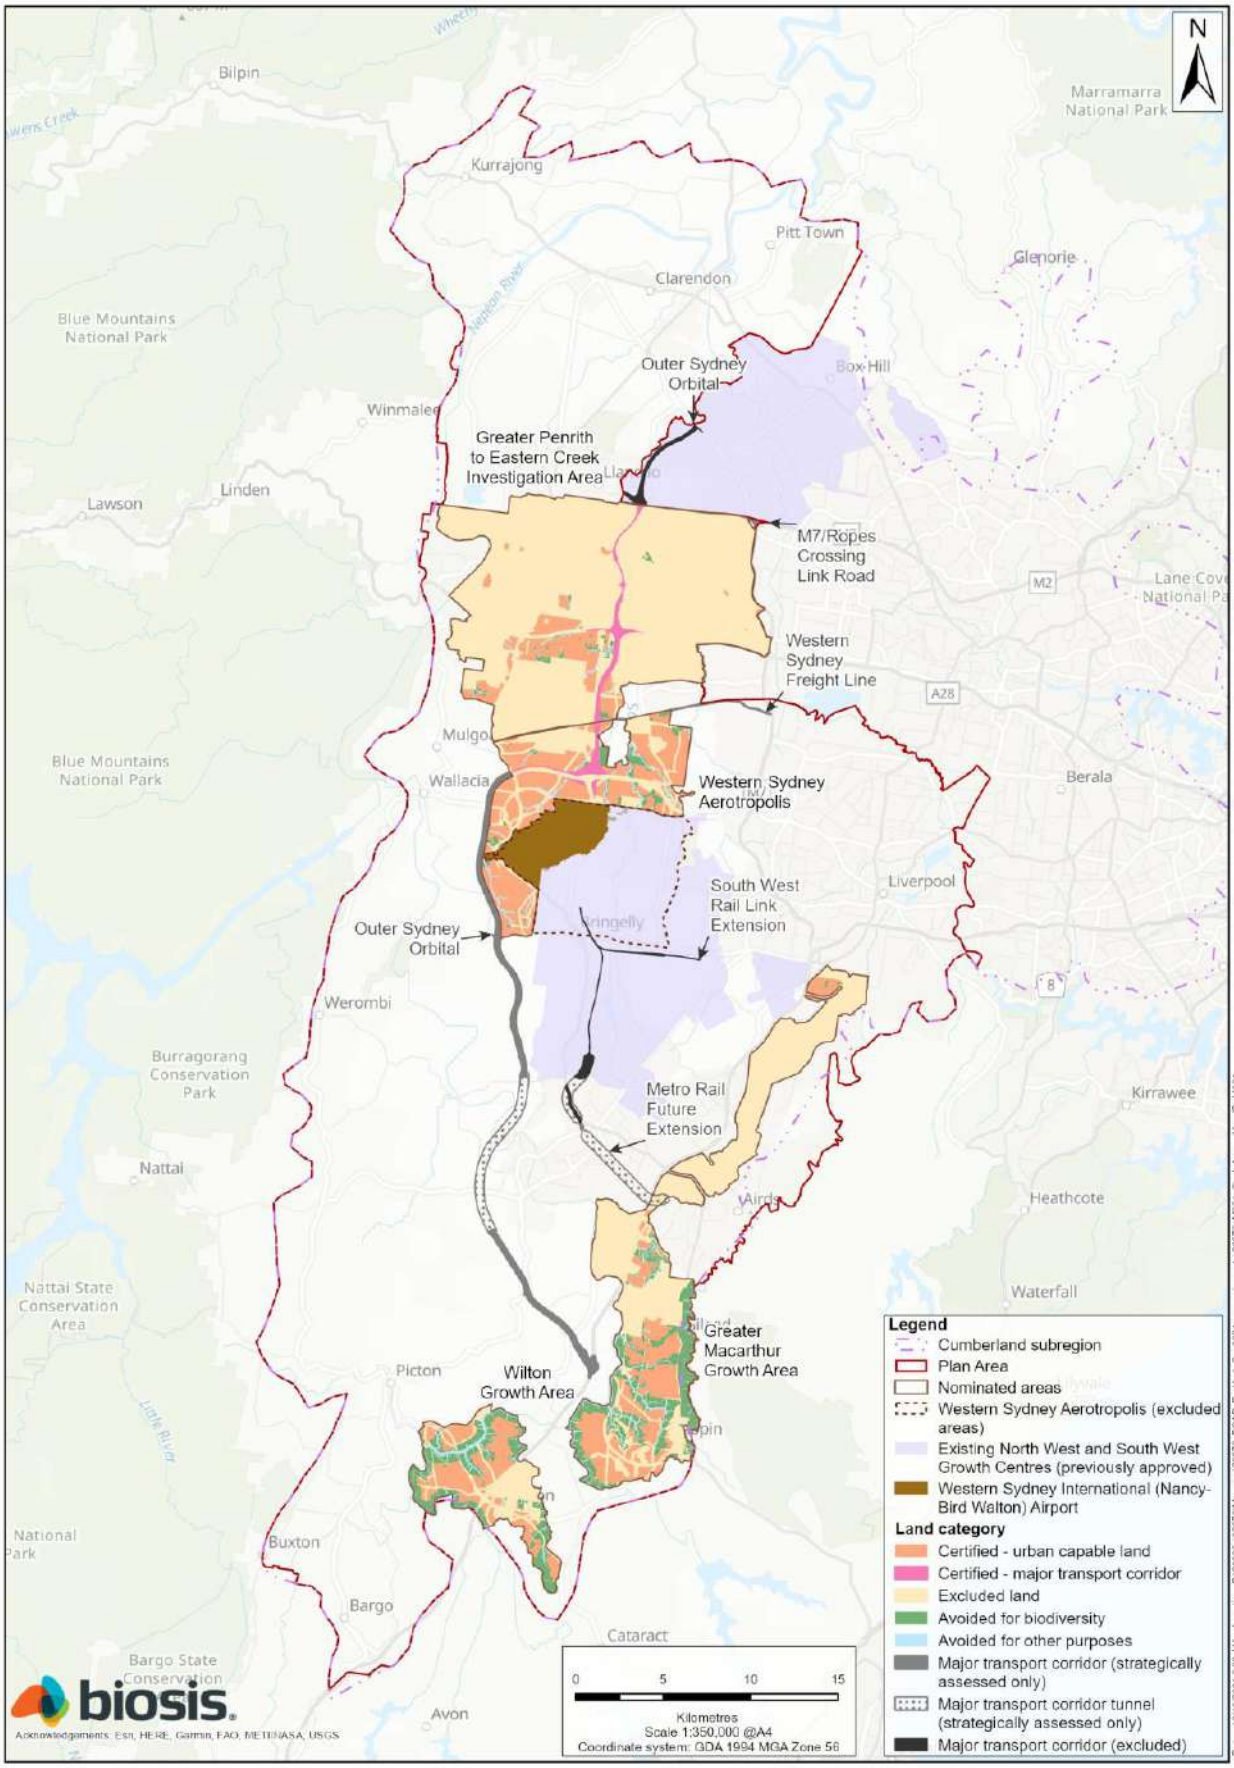

Figure 1-1: The Plan Area and location of nominated areas and major transport corridors

1.6 APPROVALS BEING SOUGHT

The Department is seeking two separate statutory approvals for the impacts of the development on biodiversity values:

- Strategic biodiversity certification under Part 8 of the BC Act
- Approval under Part 10 of the EPBC Act

Table 1-1 shows what development is subject to assessment and approval under the BC Act and EPBC Act.

Table 1-1: Development being assessed for approval under the BC Act and the EPBC Act#

Development	Biodiversity certification under BC Act	Approval under Part 10 of EPBC Act
The following development within the nominated areas: • Urban and industrial development • Infrastructure • Intensive plant agriculture • Major transport corridors – certified	✓	✓
The following development outside the nominated areas: • Major transport corridors – non-certified (strategically assessed)* • Major transport corridors tunnel – non-certified (strategically assessed)^	-	✓

Note that a formal modification to the strategic biodiversity certification will be undertaken to seek NSW biodiversity approvals on behalf of Deerubbin Local Aboriginal Land Council. This is included as an action (Action 6) under Commitment 1 of the Plan.

* Biodiversity certification may be sought for the transport corridors outside the nominated areas at a later date, and may be included as a modification or series of modifications to this biodiversity certification

^ A small part of the tunnel section of the major transport corridors occurs within a nominated area (GMAC), but this is not subject to biodiversity certification under the BC Act

Table 1-2 identifies the boundaries of the approval areas under the BC Act and EPBC Act and the effect of the approvals should they be granted.

Table 1-2: General boundaries of the approval areas under the BC Act and EPBC Act and effect of the approvals

	General boundaries of approval area	Effect of the approval
Biodiversity certification under BC Act	Land within the boundaries of the urban capable land and major transport corridors within the nominated areas shown in Figure 1-1 Land that is avoided or excluded (see Chapter 14) is not included in the land proposed to be biodiversity certified	Development can proceed in these areas without further approval under the BC Act Development must be undertaken in accordance with any conditions of the biodiversity certification under the BC Act Any other necessary approvals must also be obtained for the development, including development consent under the *Environment Planning and Assessment Act 1979* (EP&A Act)
Approval under Part 10 of EPBC Act	Land within the boundaries of the urban capable land and major transport corridors within and outside the nominated areas shown in Figure 1-1, as well as 'essential' infrastructure within avoided lands in the nominated areas	Development can proceed in these areas without further approval under the EPBC Act Development must be undertaken in accordance with the Plan and any conditions of the Part 10 approval under the EPBC Act

1.7 WHO PREPARED THIS REPORT

The Department commissioned a project team to prepare the Assessment Report and undertake data collection on biodiversity values within the Plan Area. The project team preparing this Assessment Report is comprised of:

- Open Lines – Responsible for preparing this Assessment Report, particularly the SAR component of the report
- DAJ Environmental – Part of the Open Lines team responsible for preparing this Assessment Report
- Biosis – Responsible for:
    - Preparing the BCAR component of this Assessment Report
    - Leading the collection of data to meet the requirements of the BAM and ToR
    - Developing the native vegetation, Threatened Ecological Communities (TEC) and species maps
    - Undertaking all BAM calculations to determine:
        - Amount of native vegetation, TECs and species habitat avoided and impacted
        - Number and class of biodiversity credits that would be required to be retired
- Ecoplanning – Provided support to Biosis in collecting field data to meet the requirements of the BAM and ToR

1.7.1 ACCREDITED ASSESSOR

A BCAR can only be prepared by a person accredited under the accreditation scheme developed under Section 6.10 of the BC Act. Throughout this report, an accredited person is referred to as 'the assessor'.

The BCAR component of this Assessment Report has been prepared by Jane Raithby-Veall from Biosis. Jane is a BAM accredited assessor (BAAS18134) taking the lead assessor role for the project. In preparing the BCAR, Jane has:

- Led the development of the BCAR to ensure that it meets the requirements of the BAM
- Reviewed and approved all of the data that is part of the BAM process
- Reviewed and approved all components of the BCAR

Given the size and complexity of the project, Jane was supported by a range of people in preparing the BCAR component of this Assessment Report. They include:

- Accredited BAM assessors/ecologists and GIS operators within Biosis
- Accredited BAM assessors/ecologists within Ecoplanning
- Impact assessment specialists within Open Lines and DAJ Environmental
- Technical staff within the Department's Conservation and Sustainability Branch

1.8 IMPLICATIONS OF 2019/2020 BUSHFIRES

NSW experienced extensive bushfires throughout the spring and summer of 2019-20. As of 3rd February 2020, the fires had burnt 5.37 million hectares of land (approximately 7 per cent of NSW). This includes (DPIE, 2020b):

- 37 per cent of the national park estate, including 81 per cent of the Greater Blue Mountains World Heritage Area
- 42 per cent of state forests
- 52% of heathland, 50% of wet sclerophyll and 37% of rainforest vegetation formations in NSW
- 25% of the most suitable koala habitat in eastern NSW (moderate, high and very high suitable habitat), particularly areas on the north coast, central and southern tablelands, central coast and the south coast

The full impact of the fires will not be understood for some time (EES, 2020).

Given the significance of these events, an initial assessment of the implications of the bushfires for the Plan and this Assessment Report was undertaken and is provided at Supporting Document G.

1.9 PUBLIC EXHIBITION OF THE PLAN AND ASSESSMENT REPORT

Public exhibition of the Plan and Assessment Report occurred over a period of 10 weeks from 26 August to 2 November 2020 to provide an opportunity for the community to provide feedback on the documents through formal submissions.

A total of 508 individual submissions were received from a range of stakeholders. All submissions were reviewed by the Department and consulting team and considered in preparing the final Plan and Assessment Report.

Responses to the feedback received during public exhibition as well as from early engagement on the Plan (see Part 2) were compiled into a report (see Supporting Document H). The report summarises the feedback on key themes that was received and explains how the Department has considered and responded to this feedback.

Key themes or issues raised in submissions during public exhibition that are particularly relevant to the Assessment Report and responses to these issues are summarised in Table 1-3.

Table 1-3: Key issues raised in submissions and responses to issues raised

Key theme or issue	Response to issue
E2 environmental conservation zone and the location of avoided land was based on inaccurate native vegetation mapping	Some landholders provided native vegetation mapping or ecological reports to support their submission. The information was reviewed by the accredited assessor and resulted in some minor changes to vegetation communities. This along with all reports and data provided through public exhibition was considered in updating the native vegetation and land category maps (see Chapter 11)
Impacts to Cumberland Plain Woodland are too high and remaining areas of the community should be preserved	The Assessment Report was updated to provide further information on avoidance of impacts (see Chapter 14) and residual direct impacts to Cumberland Plain Woodland (see Chapter 31) The Department will work with the Biodiversity Conservation Trust encouraging landholders to establish new biodiversity stewardship agreements in areas such as Razorback. The Razorback Area is contains significant areas of Cumberland Plain Woodland in addition to other TECs targeted for offsets under the Plan
Major transport corridors will affect existing conservation areas	The Assessment Report has evaluated the impacts of the major transport corridors on TECs and species, and the conservation program includes offsets for impacts within the corridors. A range of mitigation measures has been developed specifically to manage impacts from the construction of transport infrastructure. Transport for NSW are working to minimise impacts to existing reserves such as Wianamatta Regional Park and are proposing an elevated viaduct to pass over the reserve to reduce impacts to biodiversity values
Cumulative and indirect impacts are not adequately considered	The Assessment Report was reviewed and updated to provide further information on cumulative impacts and indirect impacts. This included considering additional major projects that could result in cumulative impacts (see Chapter 38) and providing more information about the risk of indirect impacts to specific species and TECs and the processes to implement mitigation measures (see Chapter 15)
The Plan does not go far enough to protect koala movement corridors as recommended by the Office of the NSW Chief Scientist & Engineer	The Department met with the expert panel that prepared the Advice on the protection of the Campbelltown Koala Population (Office of the NSW Chief Scientist & Engineer, 2020) to gain their insights and ensure the Plan was consistent with their recommendations The Assessment Report was reviewed and updated to reflect changes to the Plan relating to Koala (see Chapter 30) The Department is working with NSW National Parks and Wildlife Service to begin gazettal of the first stage of the Koala reserve by the end of 2023 and partnering with Transport for NSW to begin work on the fauna crossing of Appin Road to ensure safe koala movement

2 Regulatory context

This Chapter provides an overview of the key steps in the legislative processes for:

- Strategic biodiversity certification under Part 8 of the BC Act
- Strategic assessment under Part 10 of the EPBC Act

The key steps in the regulatory processes are shown in Figure 2-1.

These two processes are similar but differ in some respects. Both remove the need to further consider impacts to biodiversity values through site by site assessment and approval of individual developments.

A key difference between the two processes is that the EPBC Act process approves specific development (actions or classes of actions) undertaken in accordance with an endorsed policy, plan or program, while the BC Act process approves development within a specific area of land.

2.1 BIODIVERSITY CONSERVATION ACT 2016

2.1.1 BIODIVERSITY CERTIFICATION

Under Part 8 of the BC Act, individuals and planning authorities can seek strategic biodiversity certification from the NSW Minister for the Environment over areas of land. The biodiversity certification process requires that biodiversity values are assessed and areas of high biodiversity value are protected for conservation. Development can proceed in nominated areas with any remaining impacts on biodiversity offset through conservation measures.

Development on land that is biodiversity certified does not need further approval from planning authorities for impacts on biodiversity under the EP&A Act. In particular:

- The environmental assessment requirements for the approval of State Significant Infrastructure under Part 5.1 of the EP&A Act do not require an assessment of the impact on biodiversity
- An assessment of the likely impact on biodiversity of development is not required under Part 4 of the EP&A Act
- A consent authority is not required to take into consideration the likely impact on biodiversity when determining a development application under Part 4 of the EP&A Act
- An activity under Part 5 of the EP&A Act is taken to be an activity that is not likely to significantly affect any threatened species or ecological community under the BC Act, or its habitat
- A determining authority under Part 5 of the EP&A Act is not required to consider impacts on biodiversity

Impacts to biodiversity values on the land proposed for biodiversity certification, as well as the biodiversity benefits of the conservation program, are assessed through a BCAR. The BCAR is prepared by an accredited person in accordance with the BAM. The BCAR must be released for public comment prior to the Minister conferring biodiversity certification.

The Environment Minister may confer biodiversity certification if satisfied that the 'approved draft conservation measures' under the biodiversity certification adequately address the likely impacts on biodiversity values of the biodiversity certification, having regard to the BCAR. If the Minister is of the opinion that the biodiversity certification is likely to have serious and irreversible impacts on biodiversity values, the Minister must take those impacts into consideration and determine whether there are any additional measures that can minimise those impacts.

In determining the approved draft conservation measures under the biodiversity certification (including the number of credits that may be required to be retired), the Minister must have regard to the BCAR, but is not bound by it.

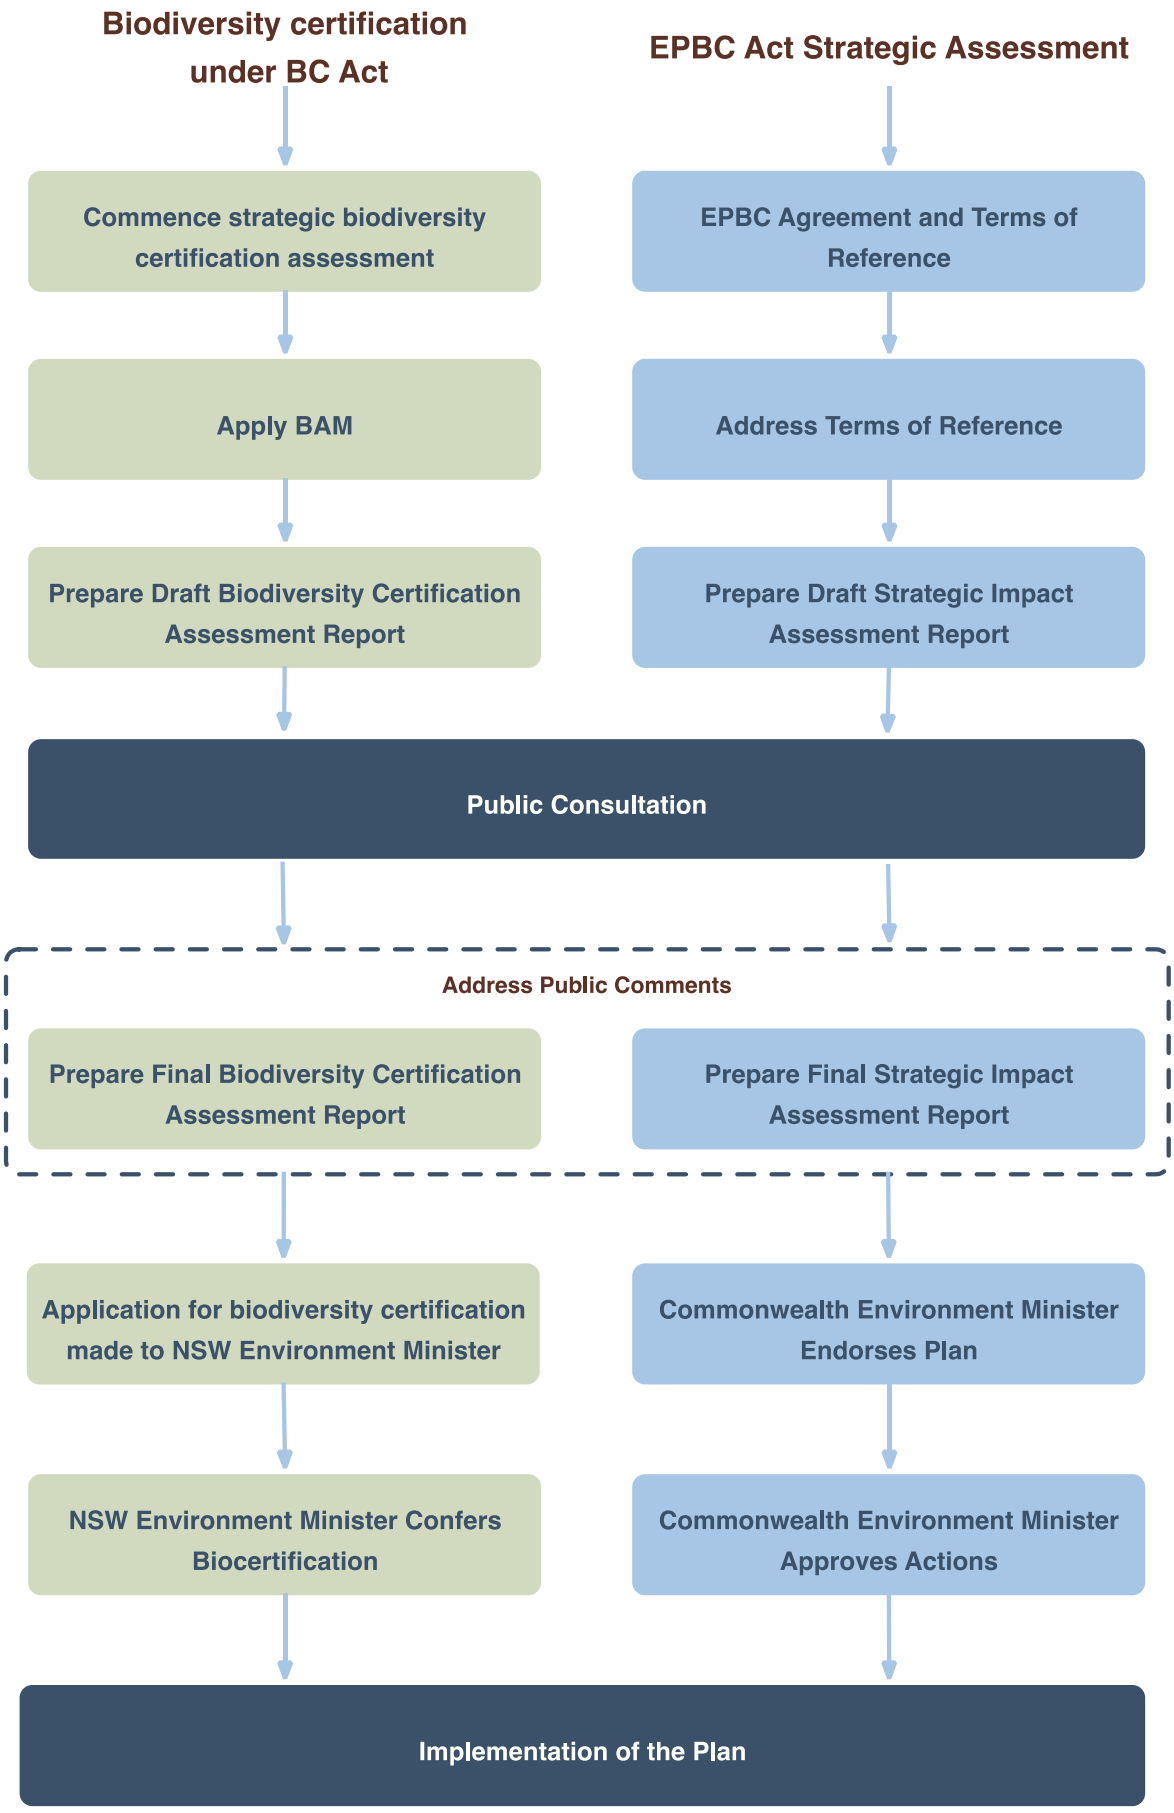

Figure 2-1: Key steps in the regulatory processes

2.1.2 STRATEGIC BIODIVERSITY CERTIFICATION

Planning authorities can apply to the Environment Minister to declare an application for biodiversity certification to be a 'strategic application'. Strategic biodiversity certification supports significant regional development and planning processes and provides an opportunity for impacts on biodiversity to be addressed at the landscape scale. In recognition of this, a wider range of conservation and other measures are available to proponents for strategic biodiversity certification to offset impacts on biodiversity values than for standard certification.

A strategic biodiversity certification may propose a mix of conservation measures that includes credits to be retired, as well as:

- Reservation of land under the *National Parks and Wildlife Act 1974* (NPW Act)
- Adoption of development controls (or State infrastructure contributions) under the EP&A Act that conserve or enhance the natural environment
- Any other measures declared by the regulations to be approved conservation measures
- Any other measure that the Minister determines to be a conservation measure

Under a strategic application for biodiversity certification, the BC Act does not require that the 'value' of the commitments be calculated in terms of credits and provides broad discretion around defining commitments. Commitments under strategic certification are not constrained by the offset rules (clause 6.2(5)(b) BC Regulation) and the NSW Environment Minister can determine any measure to be a commitment (section 8.3(2)(b) BC Act).

EES has prepared the *Conservation measures in strategic applications for biodiversity certification: Guidance for planning authorities* (DPIE, 2020a). The guidelines are intended to assist planning authorities preparing applications for strategic biodiversity certification to:

- Design conservation measures
- Demonstrate that conservation measures adequately address the likely impacts on biodiversity values of the biodiversity certification of the land

The guidelines provide principles for designing conservation measures that will be used by EES to evaluate a strategic application for biodiversity certification and advise the Environment Minister about the adequacy of conservation measures and the likely impacts on biodiversity values. These principles are summarised and addressed in Chapter 41.

When declaring that an application for strategic biodiversity certification is a strategic application, the Minister is to take into account criteria in Clause 8.3 of the BC Regulation. The criteria are:

1. The size of the area of the land
2. Any regional or district strategic plan under the EP&A Act that applies to the area in which the land is situated
3. Advice provided by the Minister for Planning regarding the proposed biodiversity certification
4. The economic, social or environmental outcomes that the proposed strategic biodiversity certification could facilitate

The Environment Minister declared on 16 January 2019 that this project is a strategic biodiversity certification.

At the time of the declaration BAM 2017 was in force, with BAM 2020 coming into effect on 22 October 2020. Under transitional arrangements, the *Biodiversity Conservation Regulation 2017* (Reg 6.31) allows the Assessment Report to be prepared under the previous biodiversity method (BAM 2017) for a designated period, stating:

"in the case of a biodiversity certification assessment report for a strategic biodiversity certification application--12 months or such longer period as the Minister approves in a particular case"

Consistent with the transitional arrangements, this Assessment Report has been prepared under BAM 2017. The Environment Minister (through a delegated authority) has approved an extension to the transitional arrangements for this project for a further 6 months, until 22 April 2022.

2.2 ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999

The EPBC Act is Australia's key piece of legislation to protect and manage Australia's nationally and internationally important flora, fauna, ecological communities, and heritage places. The objectives of the EPBC Act include:

- Providing for the protection of the environment (especially matters of national environmental significance)
- Conserving Australian biodiversity
- Providing a streamlined national environmental assessment and approvals process
- Promoting Ecological Sustainable Development (ESD) through the conservation and ecologically sustainable use of natural resources.

Under Part 10 of the EPBC Act, the Commonwealth Minister for the Environment can agree to undertake a strategic assessment of the impacts of a policy, plan or program on matters protected under the EPBC Act.

The Agreement to undertake the strategic assessment was signed by the NSW Minister for Environment and Commonwealth Minister for the Environment on 12 November 2018 (see Supporting Document A).

The agreement must provide for a ToR to guide the preparation of an Assessment Report on the impacts of the policy, plan or program. The Assessment Report must be released for public comment. The ToR outlines what the Assessment Report must contain to allow the Commonwealth Minister to endorse the Plan.

Actions undertaken in accordance with a policy, plan or program endorsed by the Environment Minister do not require further assessment and approval for impacts on protected matters under the EPBC Act.

The Environment Minister may endorse a policy, plan or program if satisfied that the Cumberland Plain Assessment Report adequately addresses the impacts on protected matters to which the agreement relates (s 146(2)(f)) and that any recommended modifications to the policy, plan or program by the Minister have been made (s 146 (2f(ii))).

The agreement between the Commonwealth Environment Minister and the State of NSW for this project (see Supporting Document A) provides that, in determining whether or not to endorse the Plan, the Minister may consider the extent to which the commitments for the protection and management of protected matters are enforceable and achievable over the life of the Plan.

The agreement also provides that, in determining whether this Assessment Report adequately addresses the impacts, the Commonwealth Environment Minister must have regard to the extent to which the Plan meets the objectives of the EPBC Act, including how the Plan:

- Protects the environment, especially protected matters under Part 3 of the EPBC Act
- Promotes ESD through the conservation and ecologically sustainable use of natural resources
- Promotes the conservation of biodiversity
- Provides for the protection and conservation of heritage
- Promotes a cooperative approach to the protection and management of the environment
- Assists in the co-operative implementation of Australia's international environmental responsibilities

Following endorsement of the Plan, the Environment Minister may approve the taking of actions in accordance with the endorsed policy, plan or program subject to a range of general considerations (s 146F) and constraints on decision making (s 146G-M), including to not act inconsistently with a recovery plan or threat abatement plan for a protected matter (s 146K).

2.3 OTHER APPROVALS REQUIRED FOR THE PROPOSED DEVELOPMENT

A range of other planning and environmental approvals may be required for the proposed development, including:

- Planning approvals under the EP&A Act
- Aboriginal cultural heritage approvals under the *National Parks and Wildlife Act 1974*
- Built heritage approvals under the *Heritage Act 1977*
- Noise, water, air pollution approvals under the *Protection of the Environment Operations Act 1997*
- Water management approvals under the *Water Management Act 2000*

- Approvals for impacts to threatened fish and other matters listed under the *Fisheries Management Act 1994*

The proposed development will be implemented through a range of existing legislative and planning frameworks, particularly the EP&A Act. Implementation arrangements are described in Part 2.

3 Overview of environment within the Plan Area

This Chapter provides a brief overview of the environment within the Plan Area, including historical land-uses. A more detailed description of the environment within the Plan Area in accordance with Section 3.1 of the ToR, including the extent and quality of native vegetation and threatening processes, is provided in Chapter 28.

3.1 HISTORICAL LAND-USES

The Cumberland subregion has been greatly affected by historical and ongoing land-uses and land management practices. This is mainly due to topographic and geological characteristics that meant the subregion could support much greater agricultural and urban development than the surrounding sandstone areas.

Before European settlement, the subregion supported diverse native vegetation, including extensive grassy open forests, ironbark and turpentine forests, dry rainforests and floodplain forest, and wetland communities. Mammals such as echidnas, quolls, phascogales, bandicoots, koalas, gliders, and bettongs would have been common, along with many woodland birds such as the Hooded Robin, Brown Treecreeper, Speckled Warbler and Diamond Firetail (DECCW, 2011).

Hundreds of records of Aboriginal sites have been found across the Cumberland subregion, suggesting the subregion was an important area for Aboriginal people materially, socially and spiritually (DECCW, 2011). Records suggest Aboriginal occupation of the Sydney region occurred for at least 20,000 years, and possibly 40,000 years (Nanson, Young et al., 1987; Stockdon, 2009; Stockton & Holland, 1974). There is evidence of extensive use of fire by Aboriginal people to manage the landscape, including to establish mosaics of native vegetation to facilitate hunting (Gammage, 2011).

European agricultural land practices were established by settlers in 1792, and by the middle of the 19th century most of the Cumberland subregion was either being grazed or cultivated (Tozer, 2003). Significant clearing for urban development, including residential, commercial and industrial land-uses, followed.

3.2 BIODIVERSITY VALUES

The biodiversity values of many parts of the Plan Area, particularly within the Cumberland subregion, have been lost or degraded as a result of both historical and ongoing patterns of land-use and land management practices.

The existing native vegetation communities in the Plan Area are shown in Figure 3-1. Existing native vegetation comprises 39 Plant Community Types (PCTs). Remaining areas are often of high conservation value. Much remaining native vegetation comprises TECs or habitat for species listed under the BC Act and EPBC Act.

Remaining native vegetation is also highly fragmented. In 2010, an estimated 2,446 individual remnants remained in the Cumberland subregion, ranging from less than one hectare to 3,598 hectares (DECCW, 2010). The eighty one largest patches (greater than 50 hectares) represent 51 per cent of the remaining native vegetation community extent (DECCW, 2011). While some flora and fauna species will persist in small native vegetation patches with active management, evidence is that larger patches have a better prospect for long-term survival (DECCW, 2011).

Evidence indicates that biodiversity loss significantly increases once habitat fragmentation by clearing exceeds 70 per cent of the landscape. This threshold has already been passed in the Cumberland subregion (DECCW, 2011). Only approximately 13 per cent of the pre-1970 extent of native vegetation in the subregion remains intact, with an additional 12 per cent occurring as heavily degraded communities (e.g. scattered trees) in disturbed areas (DECCW, 2011).

The vast majority (greater than 75 per cent) of the remaining native vegetation within the Cumberland Plain is privately owned. At 2011, approximately 8 per cent of native vegetation was protected in existing formal reserves (DECCW, 2011).

3.3 KEY THREATS

A principal threat to the biodiversity values of the Cumberland subregion is the further loss and fragmentation of habitat from clearing for urban development and agricultural land uses (DECCW, 2011), including illegal clearing.

Historial clearing has led to increasingly isolated and small remnants of native vegetation that are more susceptible to degradation, and provide less habitat values and support fewer species (DECCW, 2011).

The *Cumberland Plain Recovery Plan* (DECCW, 2011) identifies several other key threats, including:

- Weed invasion particularly by African olive, African lovegrass, and bridal creeper
- Altered fire regimes, particularly too frequent fire caused by arson
- Runoff of high-nutrient and turbid water from urban and agricultural areas

The ecological communities of the Cumberland Plain are particularly vulnerable to weed invasion due to their grassy understorey, relatively fertile soils, and past agricultural uses. Weeds such as African olive (*Olea europaea* subsp. *cuspidata*), African lovegrass (*Eragrostis curvula*) and bridal creeper (*Asparagus asparagoides*) are well established, which displaces native plants and affects the regeneration of communities (DECCW, 2011).

Stormwater carrying high nutrient and sediment loads from impermeable surfaces such as roads may runoff into areas of native vegetation, which can encourage weed invasion in addition to the soil erosion issues.

Other threats identified in the Recovery Plan (DECCW, 2011) include:

- Impacts from recreational use of areas of native vegetation
- Grazing and mowing
- Altered hydrology
- Sedimentation and erosion
- Salinity
- Impacts of climate change

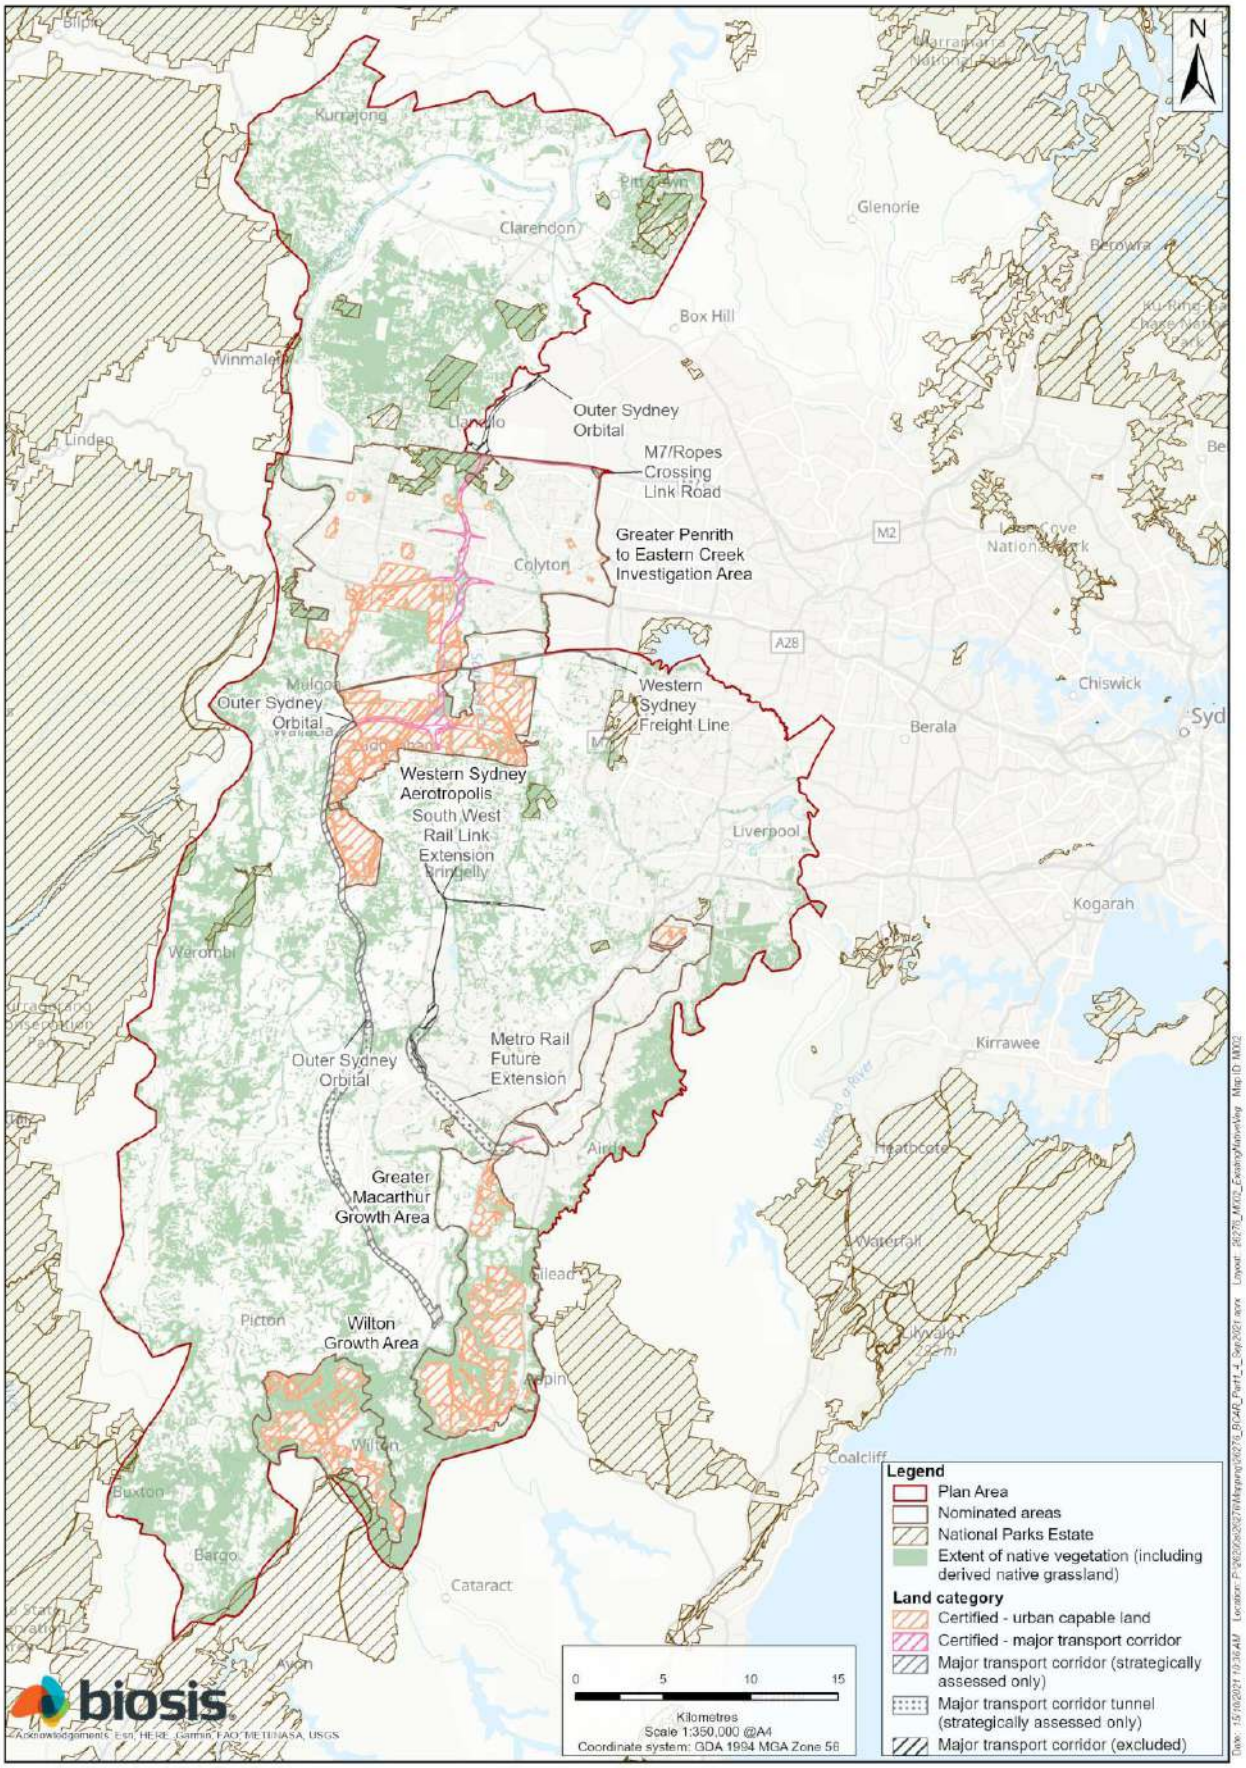

Figure 3-1: Existing native vegetation communities in the Plan Area

4 How to read this Assessment Report

BOX 1: HOW TO NAVIGATE THIS ASSESSMENT REPORT

We recommend viewing the Assessment Report using Adobe Acrobat Reader.

Adobe Acrobat Reader

- Download and install Adobe Acrobat Reader by following this link https://get.adobe.com/reader/
- Download the report and save to your computer
- Right click on the report and select 'Open with Adobe Acrobat Reader'
- Click the bookmark symbol on the left side of the Adobe interface - the headings for each report Part will appear
- Click on the > symbol next to the Part headings - the headings for each report Chapter will appear
- Navigate through the report by clicking on the Part and Chapter headings

4.1 COMPONENTS OF THE REPORT

This Assessment Report comprises both a BCAR prepared in accordance with the BAM under the BC Act and a SAR prepared in accordance with the ToR under the Part 10 Strategic Assessment Agreement of the EPBC Act.

The BCAR is mostly covered in Part 5, and the SAR part is mostly covered in Part 6. Where the requirements for preparing a BCAR and SAR are the same or similar, these requirements have been addressed jointly in a single part of this Assessment Report to avoid repetition and confusion.

Table 4-1 shows each main component of this Assessment Report and whether it forms part of the BCAR or SAR or both.

Table 4-1: Parts of this Assessment Report that comprise the BCAR or SAR or both

Report part	Description	BCAR	SAR
Part 1: Overview	Provides a general introduction to the project, this Assessment Report, and the regulatory context. Includes details of the accredited assessor (as per BC Regulation clause 6.9 (f))	✓	✓
Part 2: Description of the Cumberland Plain Conservation Plan	Describes the Plan, including its development and conservation elements, and how it will be implemented	✓	✓
Part 3: Assessment approach	Provides details of the assessment approach, including methods for identifying relevant biodiversity values that need assessing in this Assessment Report and the methods for mapping native vegetation, TECs and species habitat	✓	✓
Part 4: Minimising impacts	Provides details of the processes and actions taken to avoid and minimise impacts, an assessment of indirect impacts, and how the Plan will approach adaptive management	✓	✓
Part 5A: BCAR Stage 1 (biodiversity assessment)	Covers the requirements of Stage 1 of the BAM (existing biodiversity values) not already covered in Parts 1, 3, and 4	✓	-
Part 5B: BCAR Stage 2 (impact assessment)	Covers the requirements of Stage 2 of the BAM (assessment of impacts) not already covered in Parts 1, 3, and 4	✓	-

Report part	Description	BCAR	SAR
Part 6A: Strategic Assessment Report	Covers the requirements of the ToR relating to identifying existing biodiversity values and assessing the impacts of the Plan on protected matters not already covered in Parts 3 and 4	-	✓
Part 6B: Strategic Assessment Report			
Part 7: Evaluation of the Plan	Evaluates the adequacy of the conservation commitments and actions (as per BC Act section 8.7 and EES draft *Guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification* (DPIE, 2020a) and sections 4.6, 4.7, 5 and 6 of the ToR	✓	✓

4.2 HOW THIS REPORT ADDRESSES REGULATORY REQUIREMENTS

4.2.1 REQUIREMENTS FOR PREPARING A BCAR

The key requirements for preparing a BCAR under the BC Act are set out under:

- Part 8 of the BC Act
- Section 6.9 of the BC Regulation
- Appendix 10 of the BAM

Table 4-2 provides the key requirements for preparing a BCAR and identifies where each of these requirements are addressed in this Assessment Report, and specifically the BCAR component of this Assessment Report.

Table 4-2: Where requirements for preparing a BCAR are addressed in this Assessment Report

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Stage 1 biodiversity assessment		
Introduction		
Introduction to the biodiversity assessment: • Identification of urban capable lands • General description of development • Sources of information used in the assessment	• Site map • Location map	Chapter 7 Chapter 13 Chapter 18
Landscape context		
Identification of landscape features at the development site: • Bioregions and subregions, NSW landscape region and area • Native vegetation extent in the buffer area • Cleared areas • Rivers and streams classified according to Strahler stream order • Wetlands within, adjacent to and downstream of the site • Connectivity features • Areas of geological significance and soil hazard features • Site context components	• Site and Location maps showing landscape features	Chapter 18

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Native vegetation		
Identify native vegetation extent within the development site, including cleared areas and evidence to support differences between mapped vegetation extent and aerial imagery	• Native vegetation extent, including cleared areas	Chapter 19
Describe PCTs within the development site: • Vegetation class and type • Area (ha) for each vegetation type • Species relied upon for identification of vegetation type and relative abundance • Justification of evidence used to identify a PCT • TEC status • Per cent cleared value of PCT	• Native vegetation extent map • PCTs map • Plot locations relative to PCTs map • TECs map • Plot field data • Plot field data sheets	Chapter 19 Chapter 20
Vegetation integrity assessment of the development site: • Mapping vegetation zones • Patch size • Assessing vegetation integrity using benchmark data • Survey effort (number of plots) • Determining the vegetation integrity score	• Table of current vegetation integrity scores for each vegetation zone in development site • Patch size of intact native vegetation	Chapter 11 Chapter 19
Where use of local data is proposed: • Identify relevant vegetation type • Identify source of information for local benchmark data • Justify use of local data in preference to database values		N/A
Threatened species and habitat		
Identify ecosystem credit species associated with PCTs on development site, including: • List of species • Justification for exclusion of any ecosystem credit species	• Table of habitats/habitat components and sensitivity classes • Table of biodiversity risk weighting for species on site	Chapter 11 Chapter 21

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Identify species credit species on development site, including: • List of candidate species • Justification for inclusions and exclusions of species credit species based on habitat features • Indication of presence based on targeted survey or expert report • Details of targeted survey technique, effort, timing and weather • Species polygons • Biodiversity risk weighting for the species • Threatened species survey	• Table of list of species credit species and presence status on site as determined by targeted survey, expert report or assumed presence • Species credit species polygons map • Table of species and habitat feature/ components and abundance on site • Table of biodiversity risk weighting for species on site	Chapter 11, including Attachment A Chapter 21
Where use of local data is proposed: • Identify relevant species • Identify aspect of species data • Identify source of information for local data • Justify use of local data in preference to database values		N/A
Where expert reports are used in place of targeted survey: • Identify the relevant species • Justify the use of an expert report • Indicate and justify the likelihood of presence of the species and information considered in making this assessment • Estimate the number of individuals or area of habitat for the development site, and how the estimate was made • Identify the expert and their expert credentials	• Expert reports	Chapter 11 Chapter 21 Supporting Document C
Stage 2 Impact Assessment – Biodiversity values		
Avoid and minimise impacts		
Demonstration of efforts to avoid and minimise impact on biodiversity values in accordance with Chapter 8	• Table of measures to be implemented to avoid and minimise the impacts, including action, outcome, timing and responsibility • Urban capable land and major transport corridor map	Chapter 14

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Assessment of direct and indirect impacts unable to be avoided at the development site, including type, frequency, intensity, duration and consequence of impact	• Maps demonstrating indirect impact zones where applicable	Chapter 15 Chapter 23
Details of the adaptive management strategy proposed to monitor and respond to impacts on biodiversity values that are uncertain	N/A	Chapter 16
Impact summary		
Identification and an assessment of the impacts which are potential serious and irreversible impacts	• Map showing location of serious and irreversible impacts • Table of SAII considerations	Chapter 25
Identification of impacts requiring offset	• Map of impacts requiring offset	Chapter 26
Identification of impacts not requiring offset	• Map of impacts not requiring offset	Chapter 26
Identification of areas not requiring assessment	• Map of areas not requiring assessment	Chapter 26
Ecosystem credits and species credits that measure the impact of the development on biodiversity values, including: • Future vegetation integrity score for each vegetation zone at the development site • Change in vegetation integrity score • Number of required ecosystem credits for the impact of development on each vegetation zone at a development site • Number of required species credits for each threatened species that is impacted on by development	• Table of PCTs requiring offset and the number of ecosystem credits required • Table of threatened species requiring offset and the number of species credits required • Submitted proposal in the Credit Calculator	Chapter 26
Biodiversity credit report		
Credit classes for ecosystem credits and species credits at the development site	• Table of credit class matching credit profile	Supporting Document E

4.2.2 REQUIREMENTS FOR PREPARING A SAR

The requirements for preparing a SAR are set out under the ToR under the Part 10 Strategic Assessment Agreement.

Table 4-3 provides the key requirements for preparing a SAR and identifies where each of these requirements are addressed in this Assessment Report, and specifically the SAR component of this Assessment Report.

Table 4-3: Where requirements for preparing a SAR are addressed in this Assessment Report

Section	ToR requirement	Chapter of Assessment Report
1. Purpose of the Strategic Impact Assessment Report	1.1 The purpose of the Report is to assess the impacts of actions taken under the Cumberland Plain Conservation Plan (Plan) on all matters protected by Part 3 of the EPBC Act ('protected matters')	Chapter 1
2. Description of the Plan being assessed	2.1 The Report must describe the Plan	Part 2
	2.1.1 The Report must provide a summary outlining its overall purpose, key elements, spatial extent, and timeframes, including how long the Plan will be in effect	Chapter 1 Part 2
	2.1.2 The Report must provide details about the key elements, including: a. The conservation commitments and outcomes to be delivered for protected matters b. The actions likely to be taken under the Plan over the short, medium and long term c. The legal and administrative frameworks to implement the Plan and the persons and authorities responsible for implementation, including: i. How the Plan has been developed and its legal standing under New South Wales law. ii. The relationship of the Plan to other relevant polices, plans, guidelines, commitments, regulations and legislation including existing approvals under Commonwealth legislation for the Western Sydney Airport and the Western Sydney Growth Centres. iii. Management, approval and funding arrangements for implementing the Plan.	Chapter 5 Chapters 7 - 9
	2.1.3 The Report must describe the need and justification for the Plan including the environmental, social and economic drivers for its development	Chapter 6
	2.1.4 The Report must describe the decision-making framework used in considering alternatives and developing conservation outcomes of the Plan. It should identify where alternative options that have been evaluated to reach the final Plan have been published	Chapter 6
	2.1.5 The Report must describe how the principles of ESD (as set out in section 3A of the EPBC Act) are considered and promoted in the development of the Plan	Chapter 40
3. Description of the protected matters impacted by the Plan	3.1 The Report must describe the nature of the environment within the Strategic Assessment Area, and other areas outside the Strategic Assessment Area that may be impacted by actions taken under the Plan. This must include (at a minimum):	Chapters 28 to 31
	3.1.1 A description of historical and current land use.	Chapter 28
	3.1.2 The extent and quality of native vegetation present including detailed mapping of ecological communities and habitat for threatened species listed under the EPBC Act	Chapter 28 Chapters 29 to 31
	3.1.3 The nature of the environment, including ecosystem processes and threatening processes	Chapter 28

Section	ToR requirement	Chapter of Assessment Report
	3.1.4 A description of the landscape context for key environmental matters, including connectivity, habitat fragmentation and ecological processes	Chapter 28 Chapters 29 to 31
	3.1.5 A spatial map of areas that are already protected for environmental purposes, including Biobanking and Biodiversity Stewardship sites	Chapter 28
	3.2 The Report must identify and describe each protected matter that may be impacted directly, indirectly and cumulatively by actions taken under the Plan, including (at a minimum):	Chapter 28 Chapters 29 to 35
	3.2.1 Key sites, and where relevant, key habitats for protected matters	
	3.2.2 Important populations of protected matters, including the consideration of the importance of both small and large areas of habitat, and their position within the landscape	
	3.2.3 Areas likely to be important for maintaining ecological processes (for example, habitat connectivity) for protected matters	
	3.2.4 Condition of protected matters, including where relevant, seasonal and annual variability, and their likelihood to alter over time	
	3.2.5 Key threatening processes	
4. Assessment of the impact of the Plan on protected matters	4.1 The Report must describe and assess the likely impacts of actions taken under the Plan on all protected matters	Chapters 29 to 35
	4.2 The Report must describe the method used to understand likely impacts on all protected matters of actions taken under the Plan. The level of the assessment will be proportionate to the level of likely risk to each protected matter. The method must:	Part 3 Part 6 (Chapters 29.2, 30.2, 31.2, 32.1.2, 32.2.2, 33.6, 34.1, 35.2)
	4.2.1 Be appropriate for assessment at a strategic scale	
	4.2.2 Rely on the best available information	
	4.2.3 Discuss uncertainty, including reference to the technical data and information relied upon	Chapter 13
	4.2 The Report must identify the data used in the assessment, any limitations it may have, where (or if) the data is available and where it can be accessed, including publicly accessed	Chapter 13
	4.3 Describe and assess separately the likely impacts (if any) of actions taken under the Plan on the environment on Commonwealth land (as defined in section 528 of the EPBC Act)	Chapter 35
	4.4 The Report may also consider protected matters that are potentially eligible for listing as a result of inclusion in a final priority assessment listing held by the Commonwealth, or a recommendation to the Commonwealth Minister for listing by the Threatened Species Scientific Committee prior to the Report being submitted	Chapters 29 to 31
	4.5 The Report must include an analysis of the likely adverse impacts of actions of the Plan on protected matters. This must include (at a minimum) consideration of:	Chapters 29 to 35
	4.5.1 Information on the following: a. Number and size of populations/important populations. b. Extent (in hectares) of suitable habitat.	

Section	ToR requirement	Chapter of Assessment Report
	c. Extent (in hectares) and condition of protected matters. d. Landscape connectivity and ecological processes. e. Heritage listing and values	
	4.5.2 How impacts on protected matters will be avoided through land use planning and other measures, and what mitigation measures will be implemented to reduce impacts, including a description of the mitigation measures and how unavoidable impacts will be offset	Chapter 14 Chapters 29 to 35
	4.5.3 Potential indirect and cumulative impacts	Chapter 15 Chapters 29 to 35 Chapter 38
	4.6 The Report must include an analysis of the conservation benefits (beneficial impacts) of the Plan, including:	Chapter 8 Chapter 41
	4.6.1 How protected matters will be conserved, protected and managed within the Strategic Assessment Area and other areas related to the Plan	
	4.6.2 The adequacy of the commitments and actions under the Plan in protecting and managing protected matters, including the effectiveness of implementation and funding arrangements and who will be responsible for delivering on commitments	Chapter 9 Chapters 29 to 35 Chapter 41
	4.6.3 How proposed commitments and actions involving environmental offsets meet the principles of the *Environment Protection and Biodiversity Conservation Act, Environmental Offsets Policy*, 2012 (DSEWPC, 2012)	Chapter 41
	4.6.4 How landscape connectivity has been maintained and improved, which may include opportunities for strategic ecological restoration of key corridors and areas adjacent to sites with high biodiversity values	Chapters 29 to 35 Chapter 41
	4.6.5 How adaptation to reasonable climate change scenarios has been considered	Chapter 41
	4.7 The Report must consider the extent to which the impacts on protected matters of actions taken under the Plan meet legislative obligations under the EPBC Act, including but not limited to:	Part 6a and 6b
	4.7.1 Consistency with Australia's international obligations, including the Ramsar Convention	Chapter 33
	4.7.2 Consistency with recovery plans (section 146K of the EPBC Act)	Chapters 29 to 31
	4.7.3 Regard to objectives, conservation actions and other relevant information in conservation advices (section 146K of the EPBC Act)	Chapters 29 to 31
	4.7.4 Consistency with World Heritage management plans (sections 316 and 321 of the EPBC Act) and National Heritage place management plans (sections 324S and 324X of the EPBC Act)	Chapter 34
	4.7 The Report may also consider other Commonwealth policy guidelines on protected matters	Chapters 29 to 35
	4.8 The Report must include justification for key methods used in the assessment, including summaries of independent peer review processes and where the review/s are available to the public	Chapter 10 Chapter 11

Section	ToR requirement	Chapter of Assessment Report
5. Evaluation of the overall outcomes of the Plan	5.1 The Report must evaluate the overall commitments and outcomes for protected matters taking into account likely impacts on protected matters from actions taken under the Plan	Chapter 41
	5.2 The evaluation must include:	
	5.2.1 The extent to which protected matters are represented in areas to be protected or managed under the Plan or in existing protected areas in the bioregion/subregion	
	5.2.2 The extent to which the areas to be protected or managed under the Plan or existing protected areas in the bioregion/subregion will ensure the long-term viability of each protected matter	
	5.2.3 Whether there will be serious and irreversible impacts on any protected matter	
	5.2.4 An assessment of how the Plan meets the endorsement criteria set out in the Agreement at clause 8	
	5.3 The evaluation may also include consideration of:	
	5.3.1 The extent to which the commitments and actions under the Plan facilitate adaptation of biodiversity to climate change and address any significant vulnerabilities of protected matters under reasonable climate change scenarios	
	5.3.2 The likely effectiveness of the commitments and actions under the Plan in protecting and managing protected matters and risks and uncertainties	
6. Addressing uncertainty and adaptive management	6.1 The Report must identify key uncertainties and risks associated with implementing the Plan, responses to these and proposed adaptations to changing circumstances. Key uncertainties may include:	Chapter 9 Chapter 16
	6.1.1 Knowledge gaps in scientific understanding and responding to new knowledge	
	6.1.2 Assumptions made in assessing potential impacts and benefits	
	6.1.3 How changes to State and Commonwealth legislation, policies, plans and advice is to be accounted for in the management of the areas impacted by the Plan	
	6.1.4 Effectiveness or capacity to ensure the Plan is implemented	Chapter 16 Chapter 41
	6.2 The Report must describe and assess the adequacy of the procedures proposed in the Plan to ensure an adaptive approach to implementation of the Plan. This must include:	Chapter 16 Chapter 41
	6.2.1 How the results of monitoring will be used to understand the effectiveness of conservation outcomes for protected matters and improve implementation	
	6.2.2 How new information relating to protected matters and biodiversity, including legislative changes, may be assessed and accounted for in implementation of the Plan	
7. Monitoring and Reporting and Auditing	7.1 The Report must describe and assess the adequacy of the monitoring programs, regular review, public reporting and independent auditing processes proposed in the Plan to:	Chapter 9 Chapter 16

Section	ToR requirement	Chapter of Assessment Report
	7.1.1 Ensure conservation commitments and outcomes for protected matters contained in the Plan are delivered	Chapter 41
	7.1.2 Enable implementation of the Plan to adapt where monitoring demonstrates delivery of the conservation actions are not leading to the predicted conservation outcomes	
	7.1.3 Enable implementation of the Plan to adapt to changed circumstances, where there are risks to protected matters	
	7.2 The Report must identify and analyse the likely circumstances and procedures that may result in the review or modification of implementation plans proposed to deliver on commitments and outcomes for each protected matter as described in the Plan, or abandonment of the Plan	Chapter 9 Chapter 41
8. Information sources	8.1 The Report must identify the sources of information and data relied upon including the reliability and currency of the data	Chapter 13

CUMBERLAND PLAIN ASSESSMENT REPORT

PART 2: DESCRIPTION OF THE CUMBERLAND PLAIN CONSERVATION PLAN

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

DOCUMENT TRACKING

PREPARED BY:	
DATA:	Darren James (DAJ Environmental)
CONTENT:	Tom Holden, Peter Hemphill, Heather Tolley, Natasha Buckingham, Mitchell Ross, Stephanie Binks, Heidi Birkby, Christa Shen (Open Lines) Darren James (DAJ Environmental)
REVIEWED BY:	
OPEN LINES:	Peter Hemphill (Open Lines)
ACCREDITED ASSESSOR:	Jane Raithby-Veall (Biosis) BAM Assessor (BAAS18134)
VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 2 Contents

Part 2 List of Figures

Part 2 List of Tables

This Part describes the Cumberland Plain Conservation Plan (Plan), including:

- An introduction to the Plan (see Chapter 5)
- Planning context and need for the Plan (see Chapter 6)
- Development under the Plan (see Chapter 7)
- Conservation program of the Plan (see Chapter 8)
- Implementation framework for the Plan (see Chapter 9)

5 Introduction

This Chapter provides an introduction to the Plan, including:

- Purpose of the Plan
- Vision and objectives of the Plan
- Key elements of the Plan
- Structure of the Plan
- How the Plan was developed

5.1 PURPOSE OF THE PLAN

The purpose of the Plan is to support the planned and strategic delivery of infrastructure, housing and jobs for Western Sydney while protecting and maintaining important biodiversity areas.

The Plan is part of the NSW Government's commitment to delivering the Western Parkland City, consistent with the Greater Sydney Commission's strategic vision described in the Greater Sydney Region Plan: A Metropolis of Three Cities and Western City District Plan. This includes providing the biodiversity approvals for development in Western Sydney's four nominated areas and major transport corridors.

The Plan has been developed to meet the requirements for:

- Strategic biodiversity certification under the NSW *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act)

5.2 VISION AND OBJECTIVES OF THE PLAN

The Plan provides a high-level vision and objective and defines a set of outcomes and commitments that aim to achieve the Plan's objective and meet regulatory requirements under the BC Act and EPBC Act.

The NSW Government's vision for the Plan is to "support Western Sydney's biodiversity and growth".

The objective of the Plan is:

> *"To deliver biodiversity outcomes and support the ecological function of the Cumberland Plain, improve liveability and facilitate urban development in Western Sydney"*

5.3 KEY ELEMENTS OF THE PLAN

The Plan includes three key elements:

- Development – this covers the urban and industrial, infrastructure, intensive plant agriculture, and transport development under the Plan, including the scope and location of the development
- Conservation – this covers the conservation program and set of commitments and actions to achieve the Plan's objective and offset the impacts of the development on biodiversity values
- Implementation framework – this covers how the Plan will be implemented

The key elements of the Plan are described in detail in Chapters 7, 8 and 9 respectively.

5.4 STRUCTURE OF THE PLAN

The Plan comprises an overall Plan and two Sub-Plans.

The overall Plan describes how the development will occur and how impacts to biodiversity values and other protected matters will be addressed through the Plan's conservation program and implementation framework, including a set of commitments to address the impacts.

The Sub-Plans contain more details on how the overall Plan will be implemented, including sets of actions for each commitment that set out how the commitment will be delivered. The Sub-Plans are:

- Sub-plan A: Conservation Program and Implementation – this details the conservation program and its implementation, including the evaluation program
- Sub-plan B: Koalas – this details how the significant koala population in Western Sydney will be protected under the Plan and how the Plan will support other government initiatives to protect koala

The Plan includes a range of commitments and actions that seeks to improve ecological resilience and protect biodiversity and that will deliver the Plan's vision and objectives. These are provided in Attachment A.

5.5 HOW THE PLAN WAS DEVELOPED

5.5.1 PROGRAM LOGIC UNDERPINNING THE PLAN

The Plan was prepared on the basis of a program logic. The program logic describes how the vision, objective, outcomes, commitments and actions of the Plan link together:

- Outcomes – These are the environmental, social, and economic outcomes of the Plan
- Commitments – These set out how the outcomes are going to be delivered
- Actions – These describe what will be done to deliver the commitments

The program logic underpinning the Plan is shown in Figure 5-1.

Figure 5-1: Program logic underpinning the Plan

5.5.2 COMMUNITY CONSULTATION ON THE PLAN

Since late 2017, the Department has engaged with key stakeholders to help develop the Plan. This included local councils, landholders, industry groups, environmental groups, Local Aboriginal Land Councils (LALCs), Aboriginal groups, and members of the community. Engagement has included:

- Establishing a People's Panel in 2018 comprising of 18 community members, with at least two representatives from each of the LGAs in the Strategic Assessment Area. The Panel participated in a series of workshops on the Plan
- Establishing of a Community Reference Group comprising non-government organisations, academic and key industry stakeholders in the biodiversity conservation sector. The group included representatives from:
    - Australian Institute of Landscape Architects
    - Conservation Volunteers Australia
    - Cumberland Land Conservancy
    - Deerubbin Local Aboriginal Land Council
    - Ecological Society of Australia
    - Greening Australia
    - Landcare NSW, Mulgoa Valley Landcare Group
    - National Parks Association of NSW
    - National Trust
    - Nature Conservation Council of NSW
    - Total Environmental Centre
    - Western Sydney University, Hawkesbury Institute for the Environment
- Targeted engagement with the Aboriginal community. The Department began engaging with LALCs and the Aboriginal community about the Plan in 2018. The feedback through this engagement has supported actions in the Plan and a decision to develop and fund a 10-year Aboriginal Engagement and Implementation Strategy
- Six months of early engagement on the Plan with the Western Sydney community and key stakeholders between July and December 2019. This was done to inform stakeholders and seek preliminary feedback to support development of the Plan before was released for public exhibition
- Public exhibition of the Plan for 10 weeks from 26 August to 2 November 2020. This gave the community an opportunity to provide feedback on the draft Plan through formal submissions. A report on the community engagement process is provided as Supporting Document H

6 Planning context and need for the Plan

6.1 INTRODUCTION

The Plan has been prepared as part of a broader and complex long-term planning process for Western Sydney that aims to address a range of key planning challenges facing Greater Sydney, such as population growth and housing affordability.

This Chapter sets out:

- Key planning challenges for Western Sydney
- Planning context for Western Sydney
- Need and justification for the Plan
- Alternatives to the Plan

6.2 PLANNING CHALLENGES FOR GREATER SYDNEY

Greater Sydney is subject to several key planning challenges, including relating to:

- Population growth and housing needs, including housing affordability and choice
- Job opportunities
- Access to transport
- Protecting the natural environment and amenity

6.2.1 POPULATION GROWTH AND HOUSING NEEDS

Sydney's continued rapid growth presents a substantial challenge to urban planners. Sydney is predicted to grow by an additional 1.7 million people by 2036 (GSC, 2018a). Residents already face significant barriers to home ownership because of issues around housing affordability. In 2018, Sydney was the third least affordable major housing market for middle incomes globally, with median house prices over 11 times the median household income (Cox & Pavletich, 2019).

To accommodate this growing population, 725,000 new homes will be needed, including approximately 210,000 homes in the Western Parkland City at the centre of the Western Sydney Aerotropolis.

6.2.2 JOB OPPORTUNITIES

Sydney is predicted to have an additional 817,000 jobs by 2036. Currently there is an imbalance in the distribution of workplaces within the city, with a significant number of jobs being located within the CBD of Eastern Sydney. The concentration of jobs in one location increases the costs associated with obtaining and operating commercial premises and increases barriers to setting up or expanding business operations in Sydney (GSC, 2018a).

6.2.3 ACCESS TO TRANSPORT

The suburban layout of Sydney encourages car use over alternative transport options, such as public transport or cycling. The concentration of jobs in Eastern Sydney also means that many residents in Western Sydney are subject to long commutes. Increased travel times and heavy reliance on cars for commuting decreases the quality of life of residents by decreasing accessibility to employment and services and increasing the costs of commuting. This impacts air quality and decreases opportunities to participate in social and recreational activities (GSC, 2018a).

6.2.4 NATURAL ENVIRONMENT AND AMENITY

The natural environment and built heritage of Western Sydney provides important social, cultural, aesthetic, economic, historic, and environmental values within the Sydney region. The environment of Western Sydney is under significant pressure from historical and proposed new land uses (see Chapter 3 in Part 1) and balancing the protection of the environment and heritage with other urban development objectives is a significant planning challenge.

6.3 PLANNING CONTEXT FOR WESTERN SYDNEY

The NSW Government has prepared several strategies and plans to address the key planning challenges facing Greater Sydney in a coordinated and strategic manner. The key strategies and plans that form part of this planning framework, and their relationship to each other and the Plan, are discussed below.

6.3.1 WESTERN SYDNEY CITY DEAL

The Western Sydney City Deal is the single largest planning, investment and delivery partnership in the history of Australia, and involves the Australian and NSW Governments and eight local Councils in Western Sydney (GSC, 2018b). The Deal supports additional jobs, housing, and liveability improvements in Western Sydney.

Under the City Deal, the NSW Government has committed to publish 5-year and 20-year housing targets for each local government area to deliver 185,000 new homes needed in the next 20 years.

The City Deal supports the delivery of the Western City District Plan that covers the nominated areas, and includes a commitment to conduct a strategic assessment under the EPBC Act to protect the environment and streamline environmental approvals for development in Western Sydney (DIRDC & DPC, 2018).

The Plan supports that commitment by providing a mechanism to undertake this strategic assessment.

6.3.2 GREATER SYDNEY REGION PLAN

The Greater Sydney Region Plan is a 40-year vision for a global metropolis of three cities incorporating land use planning, transport planning and infrastructure planning. The Region Plan sets out a plan to manage urban growth by establishing a 'metropolis of three cities': Western Parkland City, Central River City, and Eastern Harbour City.

The Region Plan supports the delivery of the Western Parkland City by facilitating the nominated areas and major transport corridors. The Region Plan also includes an action (number 72) to deliver strategic conservation planning and develop a conservation plan for Western Sydney. The Cumberland Plain Conservation Plan delivers on that action.

The Region Plan is guided by 10 overarching directions and 40 objectives for liveability and sustainability, productivity and infrastructure in Greater Sydney and includes a target that all homes will be within 30 minutes access to jobs, schools, and health care (GSC, 2018a). Two core directions address sustainability:

- A cool and green parkland city in the Wianamatta (South Creek) corridor (Objective 26)
- Biodiversity is protected, urban bushland and remnant vegetation is enhanced (Objective 27)

The Region Plan is supported by a series of five 20-year District Plans. These District Plans provide greater detail regarding planning, development, and conservation objectives for each district of Sydney.

By supporting the delivery of the Western Parkland City, the Cumberland Plain Conservation Plan will contribute to the wider objective to develop Sydney as a 'polycentric city' and therefore help address many key planning challenges outlined in Section 6.2. Monocentric cities that experience growth can suffer from increasing business costs, increased housing and living costs, increased labour costs and reduced labour supply, and social segregation, congestion, air quality problems, heat island effects and spatial polarisation (GSC, 2018a). Major cities are responding to planning challenges associated with city growth through promoting the development of polycentric city structures (GSC, 2018a).

6.3.3 WESTERN SYDNEY DISTRICT PLAN

The relevant District Plan for the area covered by the Cumberland Plain Conservation Plan is the Western City District Plan. The Western City District Plan aligns with the Greater Sydney Region Plan and provides more details regarding targeted planning objectives for the District, with associated actions to be undertaken to achieve the outlined objectives.

The Cumberland Plain Conservation Plan supports the implementation of Western City District Plan's planning priorities for:

- Creating a Parkland City urban structure and identity, with Wianamatta (South Creek) corridor as a defining spatial element (Priority W13)
- Protecting and enhancing bushland and biodiversity (Priority W14)
- Protecting and enhancing scenic and cultural landscapes (Priority W16)

6.3.4 FUTURE TRANSPORT STRATEGY 2056

The Future Transport Strategy 2056 is an overarching strategy to achieve a series of objectives for the NSW transport network (Transport for NSW, 2018). The Transport Strategy will be implemented by a suite of plans, including the Greater Sydney Services and Infrastructure Plan (Transport for NSW, 2018).

The Future Transport Strategy 2056 supports the development of Sydney as a polycentric city by developing an integrated network of transport corridors to support connectivity and liveability within Sydney.

The Transport Strategy identifies a range of transport initiatives for investigation, including the Outer Sydney Orbital identified under this Plan (Transport for NSW, 2018).

The Plan supports the delivery of these transport initiatives in Western Sydney.

6.4 NEED AND JUSTIFICATION FOR THE PLAN

This Section addresses section 2.1(3) of the ToR, which requires the Assessment Report to '…describe the need and justification for the Plan including the environmental, social and economic drivers for its development'.

The Plan is needed for the following four key reasons:

- Supports the delivery of the nominated areas program and major transport corridors
- Supports the delivery of key planning strategies and plans
- Provides a mechanism to address conservation challenges for the Cumberland subregion
- Supports NSW Government priorities

6.4.1 SUPPORTS THE DELIVERY OF THE NOMINATED AREAS PROGRAM AND MAJOR TRANSPORT CORRIDORS

The Plan supports the delivery of the NSW Government nominated areas program and the development of major transport infrastructure to meet the long-term transport needs of Western Sydney.

The nominated areas program represents the strategic prioritisation and delivery of new development as part of the long-term growth of Greater Sydney and to meet key social and economic objectives identified under the Greater Sydney Region Plan. The program will consolidate future development needs across Western Sydney by establishing four new nominated areas. The nominated areas are the key focus for urban development over the coming decades and will be the centres of economic and social activity in Western Sydney.

Future Transport 2056 identifies a series of major transport corridors for the coming decades. For Western Sydney, major transport infrastructure is planned to be delivered to respond to the economic and social needs of Western Sydney over the next 40 years. The Plan includes key Western Sydney (major) transport corridors to facilitate infrastructure projects that will generate economic activity and support employment opportunities in the region.

6.4.2 SUPPORTS DELIVERY OF KEY PLANNING STRATEGIES AND PLANS

The Plan supports the delivery of key planning strategies and plans for Western Sydney, as well as the Western City Deal. By supporting the delivery of these, the Plan is directly helping to address key environmental, social, and economic planning challenges facing Greater Sydney outlined in Section 6.2.

The key plans and strategies that the Plan is supporting, and how the Plan supports their delivery, are outlined in Section 6.3. In summary, the Plan is needed to support implementation of:

- Western Sydney City Deal – by providing the mechanism to conduct a strategic assessment under the EPBC Act to protect the environment and streamline environmental approvals for development in Western Sydney
- Greater Sydney Region Plan, by supporting the delivery of the:
    - Western Parkland City
    - Key objectives of the Region Plan, including:
        - A cool and green parkland city in the Wianamatta (South Creek) corridor (Objective 26)
        - Biodiversity is protected, urban bushland and remnant vegetation is enhanced (Objective 27)

- Western City District Plan, by supporting the delivery of planning priorities:
  - Creating a Parkland City urban structure and identity (Priority W13)
  - Protecting and enhancing bushland and biodiversity (Priority W14)
  - Protecting and enhancing scenic and cultural landscapes (Priority W16)
- NSW Koala Strategy in Western Sydney

6.4.3 PROVIDES A MECHANISM TO ADDRESS CONSERVATION CHALLENGES FOR CUMBERLAND SUBREGION

Conservation planning in the Cumberland subregion is challenging and complex. Biodiversity in the subregion has suffered significant disturbance, and the subregion is one of the most threatened regions in NSW (DEC, 2005). Many ecological communities and species are listed as threatened under both NSW and Commonwealth legislation. Areas of remaining native vegetation are often of high conservation value. At the same time, the population of Sydney is growing, housing affordability is a priority and the cost of land across the region is very high.

These issues make it challenging to identify options that satisfy regulatory and community expectations around biodiversity conservation while also addressing the need for cost effective development.

Strategic assessment processes provide significant opportunities to address the key conservation challenges in the Cumberland subregion while facilitating cost effective development.

Strategic assessments can have the following benefits:

- Streamline the assessment and approval process and reduce duplication between regulatory requirements
- Enable effort to be focused on the highest biodiversity value areas of the landscape
- Address ecological function and landscape-scale ecological processes, such as habitat connectivity
- Manage threats at a landscape scale that can maximise benefits to multiple species
- Be designed and implemented strategically, such as by consolidating offsets into large and more viable patches
- Be implemented ahead of impacts occurring from development, to help reverse any trend of decline

6.4.4 SUPPORTS NSW GOVERNMENT PRIORITIES

The Plan supports NSW Government priorities and in particular, the Premier's Priorities. The Plan supports the delivery of two Premier's Priorities:

- Greening our city—increase tree canopy and green cover across Greater Sydney by planting 1 million trees by 2022
- Greener public spaces—increase the proportion of homes in urban areas within 10 minutes' walk of quality green, open and public space by 10% by 2023

The Plan contributes to these priorities by establishing and protecting large areas of new conservation land within Western Sydney, including new public reserves, and introducing development controls to protect biodiversity and other environmental features in urban development areas that will support increasing canopy and green cover.

6.5 ALTERNATIVES TO THE PLAN

This section addresses section 2.1(4) of the ToR, which requires the Assessment Report to '…describe the decision-making framework used in considering alternatives and developing conservation outcomes of the Plan.

Alternatives to the Plan can be discussed in terms of:

- Alternative approaches to urban development
- Alternative conservation outcomes
- Alternative locations of the urban capable lands and major transport corridors

The ToR requires the Assessment Report to '…identify where alternative options that have been evaluated to reach the final Plan have been published'. A key early step in considering alternative conservation outcomes was a structured decision-making process. There is no published report on this process, however, the process and its results are summarised in section 6.5.2. The various strategic planning processes and plans that considered and lead to the proposed locations for the urban capable land and major transport corridors are referenced in section 6.5.3.

6.5.1 ALTERNATIVE APPROACHES TO URBAN DEVELOPMENT

The nominated areas program involves the identification of large areas for greenfield development in high-level strategic planning documents. The nominated areas represent a planned approach to land release for which the NSW Government takes a lead role in setting objectives, planning, and co-ordinating the delivery of development.

Developing nominated areas provides the most effective approach to address the key planning challenges facing Sydney as it provides for a considered and strategic approach to the location of urban and transport infrastructure. A planned approach to land release through nominated areas also allows for:

- Co-ordinated precinct structure planning and better integration of land use and transport to maximise social and economic benefits, including employment areas, schools, hospitals, transport precincts, and open space
- More effective investment by infrastructure agencies when planning for services
- Better co-ordination and alignment between the objectives of different government agencies
- Better direction for the development industry about where future development will occur and greater certainty for landowners about the future use of their land
- A co-ordinated approach to development contributions to help fund the delivery of key infrastructure
- A more efficient use of government resources in responding to development proposals

The alternative to developing nominated areas is a larger number of smaller urban precincts that are separately identified and planned by different planning authorities across a broader region. This approach does not provide the benefits that come with the co-ordinated planning and consolidated development within nominated areas.

6.5.2 ALTERNATIVE CONSERVATION OUTCOMES

The Department applied a structured decision-making process during early development of the Plan to define a high-level biodiversity outcome for the Cumberland subregion that set the context and direction for the development of the Plan. The structured decision-making was one of the first steps in a comprehensive conservation planning process for the Plan. Other planning processes included a process to avoid impacts to biodiversity values (see Chapter 14) and a method to identify high value conservation lands within the Cumberland subregion for offsets that best support an ecologically-functioning, connected landscape (called the Conservation Priorities Method – see Sub-Plan A).

The structured decision-making process provided a systematic method to identify and compare a range of conservation options available to the NSW Government, taking into account social, economic, and environmental considerations.

The structured decision-making process involved five steps:

1. Understanding the decision/s that need to be made
2. Identifying what is important when making those decision/s
3. Developing a range of alternatives to compare
4. Understanding the performance of different alternatives
5. Comparing options and selecting a preferred alternative

The key decision relevant to the structured decision-making work was:

> *"What is the optimal biodiversity outcome for Western Sydney that will enable planned and existing development (including both in and beyond the nominated areas in the Cumberland Plain) to proceed in an affordable and sustainable way?"*

The structured decision-making process was based around four decision making criteria and six performance measures across environmental, social, and economic themes. The criteria were:

- Maximise conservation of biodiversity
- Minimise the costs of delivering the biodiversity outcome
- Ensure the biodiversity outcome is feasible
- Maximise public amenity

The process looked at four different models to provide funding for the biodiversity outcome, examined twenty alternative biodiversity outcomes, modelled the performance of each alternative, and compared the twenty alternatives under various scenarios to reach conclusions about the optimal approach.

The process found that the best approach to achieving the optimal biodiversity outcome with the available funding is to apply a broad mix of commitments and actions to maximise the biodiversity values that are protected, maximise certainty of delivery and alleviate the pressure on offset supply and demand.

The best mix of approaches includes:

- Securing one or more new national parks in the Plan Area
- Investing in biodiversity stewardship in the best remaining vegetation in the Plan Area
- Restoring key parts of the landscape within the Plan Area
- Providing dedicated funding for a set of actions to protect Koalas
- Investing a smaller proportion of the funding on biodiversity stewardship outside the Plan Area, within the allowable variation rules under the BC Regulation

This mix of approaches is reflected in the conservation program for the Plan (see Chapter 8).

6.5.3 ALTERNATIVE LOCATIONS OF URBAN CAPABLE LANDS AND MAJOR TRANSPORT CORRIDORS

PROCESSES TO LOCATE THE URBAN CAPABLE LAND

The urban capable land was identified in three phases:

- Strategic planning to locate the nominated areas
- Initial development of footprints through Land Use and Infrastructure Implementation Plans
- Iterative refinement of the footprints through development of the Plan and assessment of impacts

The initial development and refinement of the urban capable land footprints is described in Chapter 14.

Strategic planning to locate the nominated areas

The broad location of the nominated areas was determined through various strategic planning strategies and investigations over many years. Two key planning strategies that informed the location of the nominated areas were:

- *A Plan for Growing Sydney* (DPE, 2014) – this identified the general location of Wilton Growth Area (Wilton) and Greater Macarthur Growth Area (GMAC) and the Badgerys Creek Airport precinct, which was subsequently refined further by the Department to become WSA
- *A Metropolis of Three Cities* (GFC, 2017) – this identified the general location of Greater Penrith to Eastern Creek Investigation Area (GPEC) and establishes a 40-year vision for Sydney as a global metropolis of three cities, including the Western Parkland City covering the nominated areas

The nominated areas were located based on a broad range of strategic planning considerations, including:

- Proximity to current and planned locations of employment
- The cost of infrastructure provision including roads, water, sewerage, public transport, schools, and health facilities
- The economic and social cost to communities of having poor access to employment and services, including transport
- Environmental constraints, including biodiversity values

Action 2.4.2 of *A Plan for Growing Sydney* (DPE, 2014) aimed to develop a long-term framework for the identification of new nominated areas to improve the management of future land release in Sydney. In preparing a framework for the identification of nominated areas, Action 2.4.2 indicates that a range of issues should be considered, including:

- The value of land for drinking water supply, agriculture, environmental management, and other purposes
- Constraints to development, including environmental constraints and natural hazards

The Department undertook investigations into the location of the nominated areas in accordance with Action 2.4.2.

PROCESSES TO LOCATE THE MAJOR TRANSPORT CORRIDORS

The process for identifying, selecting, and designing future corridors and transport projects involves a detailed set of steps and processes to ensure optimum infrastructure, environmental, social and economic outcomes are achieved. The *Planning guideline for Major Infrastructure Corridors* (DPE, 2016) sets out the recommended processes for infrastructure agencies to follow through the different phases of corridor planning.

The guideline provides advice in relation to the three broad phases:

- Strategic planning – identification
- Corridor planning and selection
- Infrastructure delivery

The first two phases lead to the identification and protection of major transport corridors. As part of this process, a Strategic Environmental Assessment (SEA) is prepared which provides an assessment of the environmental, economic and social impacts of reserving the corridor. SEAs are non-statutory documents that assist in the planning and decision-making process for the community and Government. They are subject to public consultation and include justification for a preferred corridor alignment and provide information on the assessment of alternative corridor alignments.

In making decisions on corridor selection, infrastructure agencies undertake a constraints analysis and multi-criteria comparison of options. These include consideration of a wide range of factors including:

- Aboriginal heritage
- Biodiversity
- Costs
- Engineering and construction limitations
- Land use and property impacts
- Landscape character and visual amenity
- Noise and vibration
- Non-Aboriginal heritage
- Socio-economic considerations
- Soils, geology, and contamination
- Transport planning
- Water quality and hydrology

Refer to Chapter 14 for an example of the process used to locate the Outer Sydney Orbital (OSO) (AECOM, 2018).

7 Development under the Plan

7.1 INTRODUCTION

This Chapter describes each of the development elements of the Plan.

An overview of the development under the Plan is provided in Section 1.5 of Part 1. Part 1 (Section 1.6) also describes the scope and boundaries of the approvals being sought by the Department for the development under the BC Act and EPBC Act.

7.1.1 DEVELOPMENT UNDER THE PLAN

The Plan provides for the following development:

- Urban and industrial development within urban capable land in the nominated areas
- Infrastructure within urban capable land in the nominated areas, as well as 'essential' infrastructure in limited cases within avoided lands in the nominated areas
- Intensive plant agriculture within the Western Sydney Aerotropolis agribusiness precinct
- Major transport corridors within and outside the nominated areas

Each type of development is described in detail in sections 7.2 to 7.5. The development is described in terms of actions that are to be included in an approval of a class of actions pursuant to section 146 of the EPBC Act.

The location of these developments is shown in Part 1 (Figure 1-1).

7.1.2 APPROVALS SOUGHT UNDER THE PLAN

As discussed in Part 1, the Department is seeking two separate statutory approvals for the impacts of the urban and industrial development, infrastructure, intensive plant agriculture and major transport corridors on biodiversity values:

- Strategic biodiversity certification under Part 8 of the BC Act
- Approval under Part 10 of the EPBC Act

Table 7-1 shows what development is subject to assessment and approval under the BC Act and EPBC Act.

Table 7-1: Development being assessed for approval under the BC Act and the EPBC Act#

Development	Biodiversity certification under BC Act	Approval under Part 10 of EPBC Act
The following development within the nominated areas: • Urban and industrial development • Infrastructure, including essential infrastructure* • Intensive plant agriculture • Major transport corridors – certified	✓*	✓
The following development outside the nominated areas: • Major transport corridors – non-certified (strategically assessed)** • Major transport corridors tunnel – non-certified (strategically assessed)^	-	✓

Note that a formal modification to the strategic biodiversity certification will be undertaken to seek NSW biodiversity approvals on behalf of Deerubbin Local Aboriginal Land Council. This is included as an action (Action 6) under Commitment 1 of the Plan. *

* Essential infrastructure is a subset of the infrastructure class of action, and relates to development of essential infrastructure within avoided lands within the nominated areas. Essential infrastructure is to be assessed for approval under Part 10 of the EPBC Act only, and is not included in the biodiversity certification under the BC Act

** Biodiversity certification may be sought for the transport corridors outside the nominated areas at a later date, and may be included as a modification or series of modifications to this biodiversity certification

^ A small part of the tunnel section of the major transport corridors occurs within a nominated area (GMAC), but this is not subject to biodiversity certification under the BC Act

7.1.3 MAJOR DEVELOPMENT NOT PART OF THE PLAN

The following major urban and transport development occur within the Plan Area but are not part of this strategic biodiversity certification and strategic assessment process as they have been previously assessed and approved, or are currently being assessed and considered for approval, under NSW and Commonwealth laws:

- Existing North West and South West Growth Areas (previously assessed and approved)
- Western Sydney International (Nancy-Bird Walton) Airport (previously assessed and approved)
- Sydney Metro Stage 1

7.2 URBAN AND INDUSTRIAL DEVELOPMENT

7.2.1 DESCRIPTION OF THE DEVELOPMENT

The Plan provides for urban and industrial development in four nominated areas:

- Wilton Growth Area (Wilton)
- Greater Macarthur Growth Area (GMAC)
- Western Sydney Aerotropolis (WSA) (excluding where there is overlap with the existing South West Growth Area)
- Greater Penrith to Eastern Creek Investigation Area (GPEC)

The nominated areas are shown in Figure 7-1 to Figure 7-4.

Urban and industrial development will be confined to the urban capable land within the nominated areas.

Other land within the nominated areas includes:

- Land covered by the major transport corridors
- Land avoided for development because of its biodiversity value (see Chapter 14)
- Land avoided for development for other reasons (e.g. because it is unsuitable for development)
- Land that is already protected or developed, or otherwise not included in the Plan (excluded land)

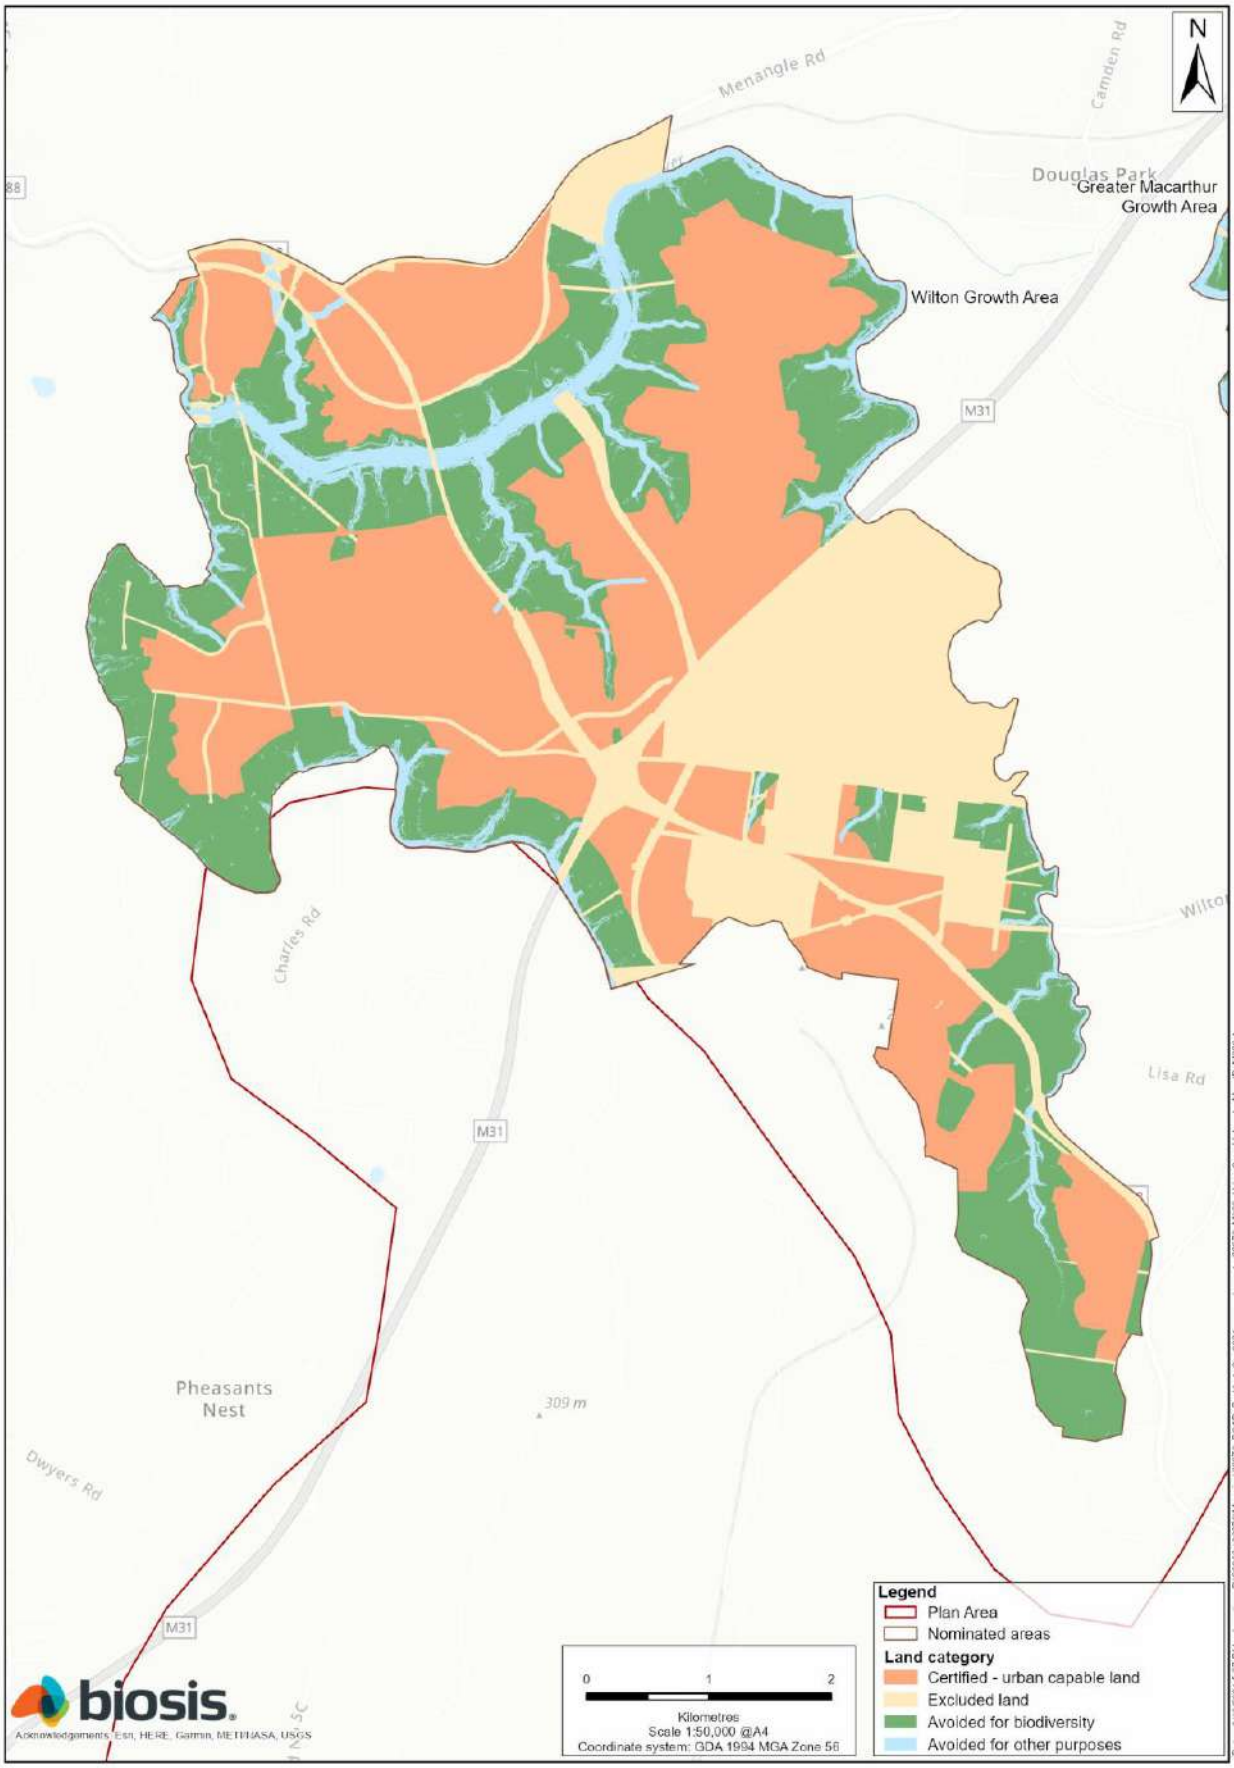

Figure 7-1: Urban capable land within Wilton Growth Area

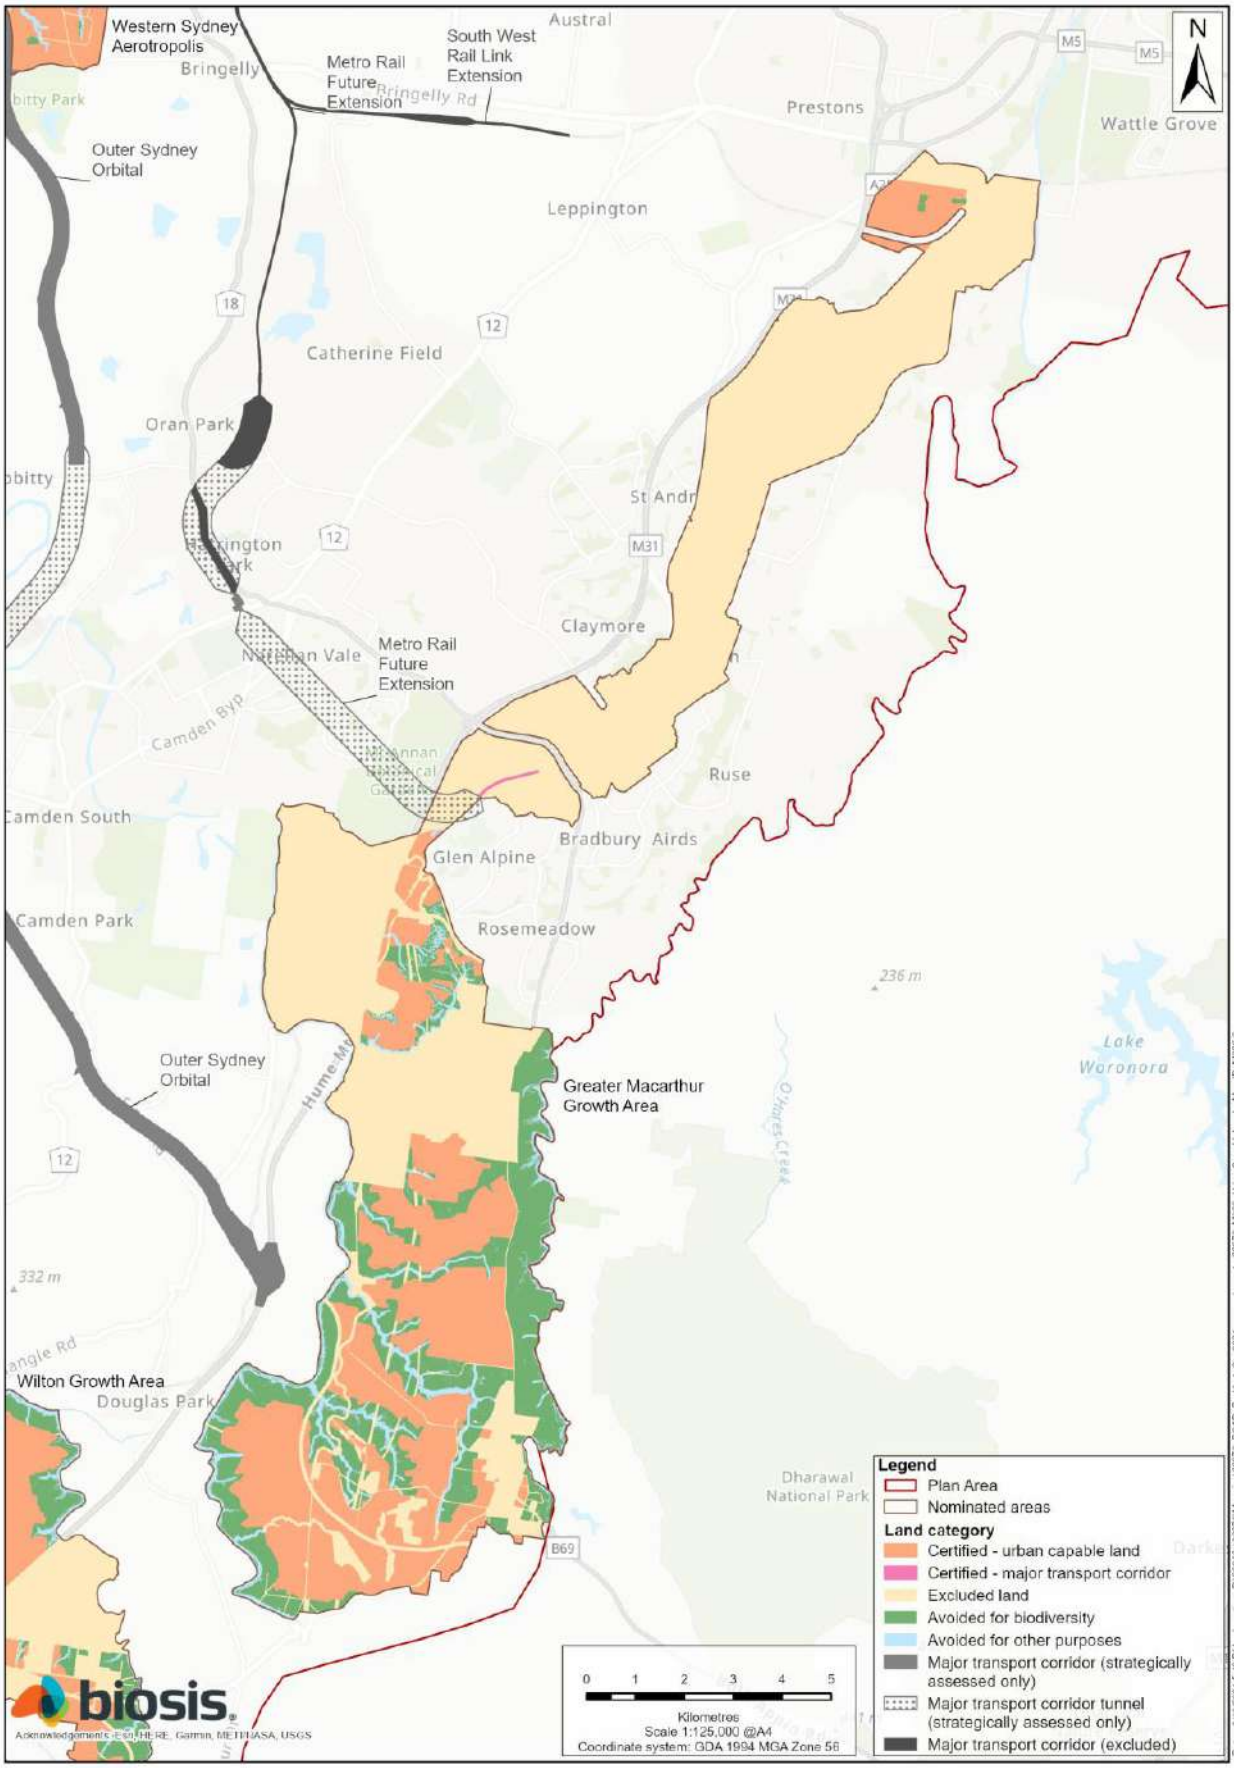

Figure 7-2: Urban capable land within GMAC

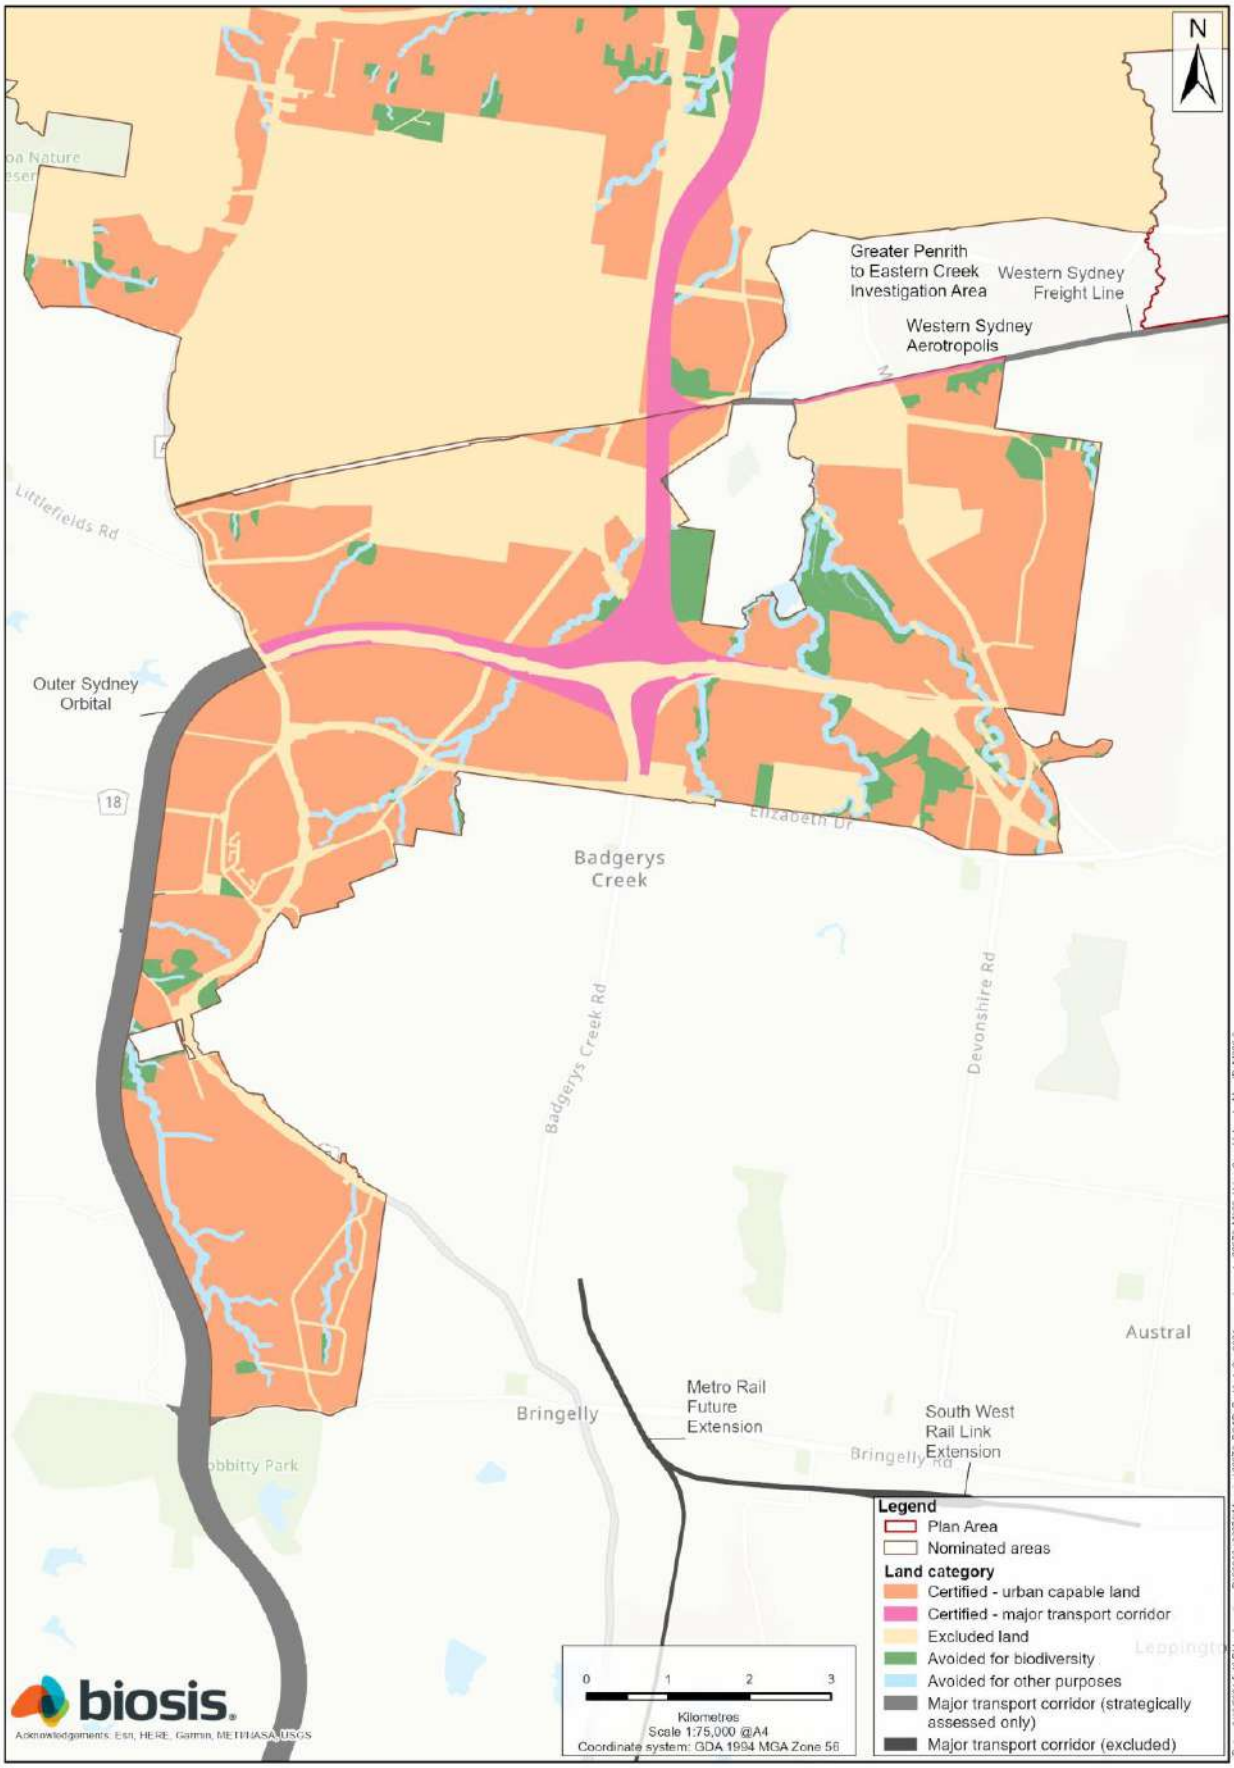

Figure 7-3: Urban capable land within WSA

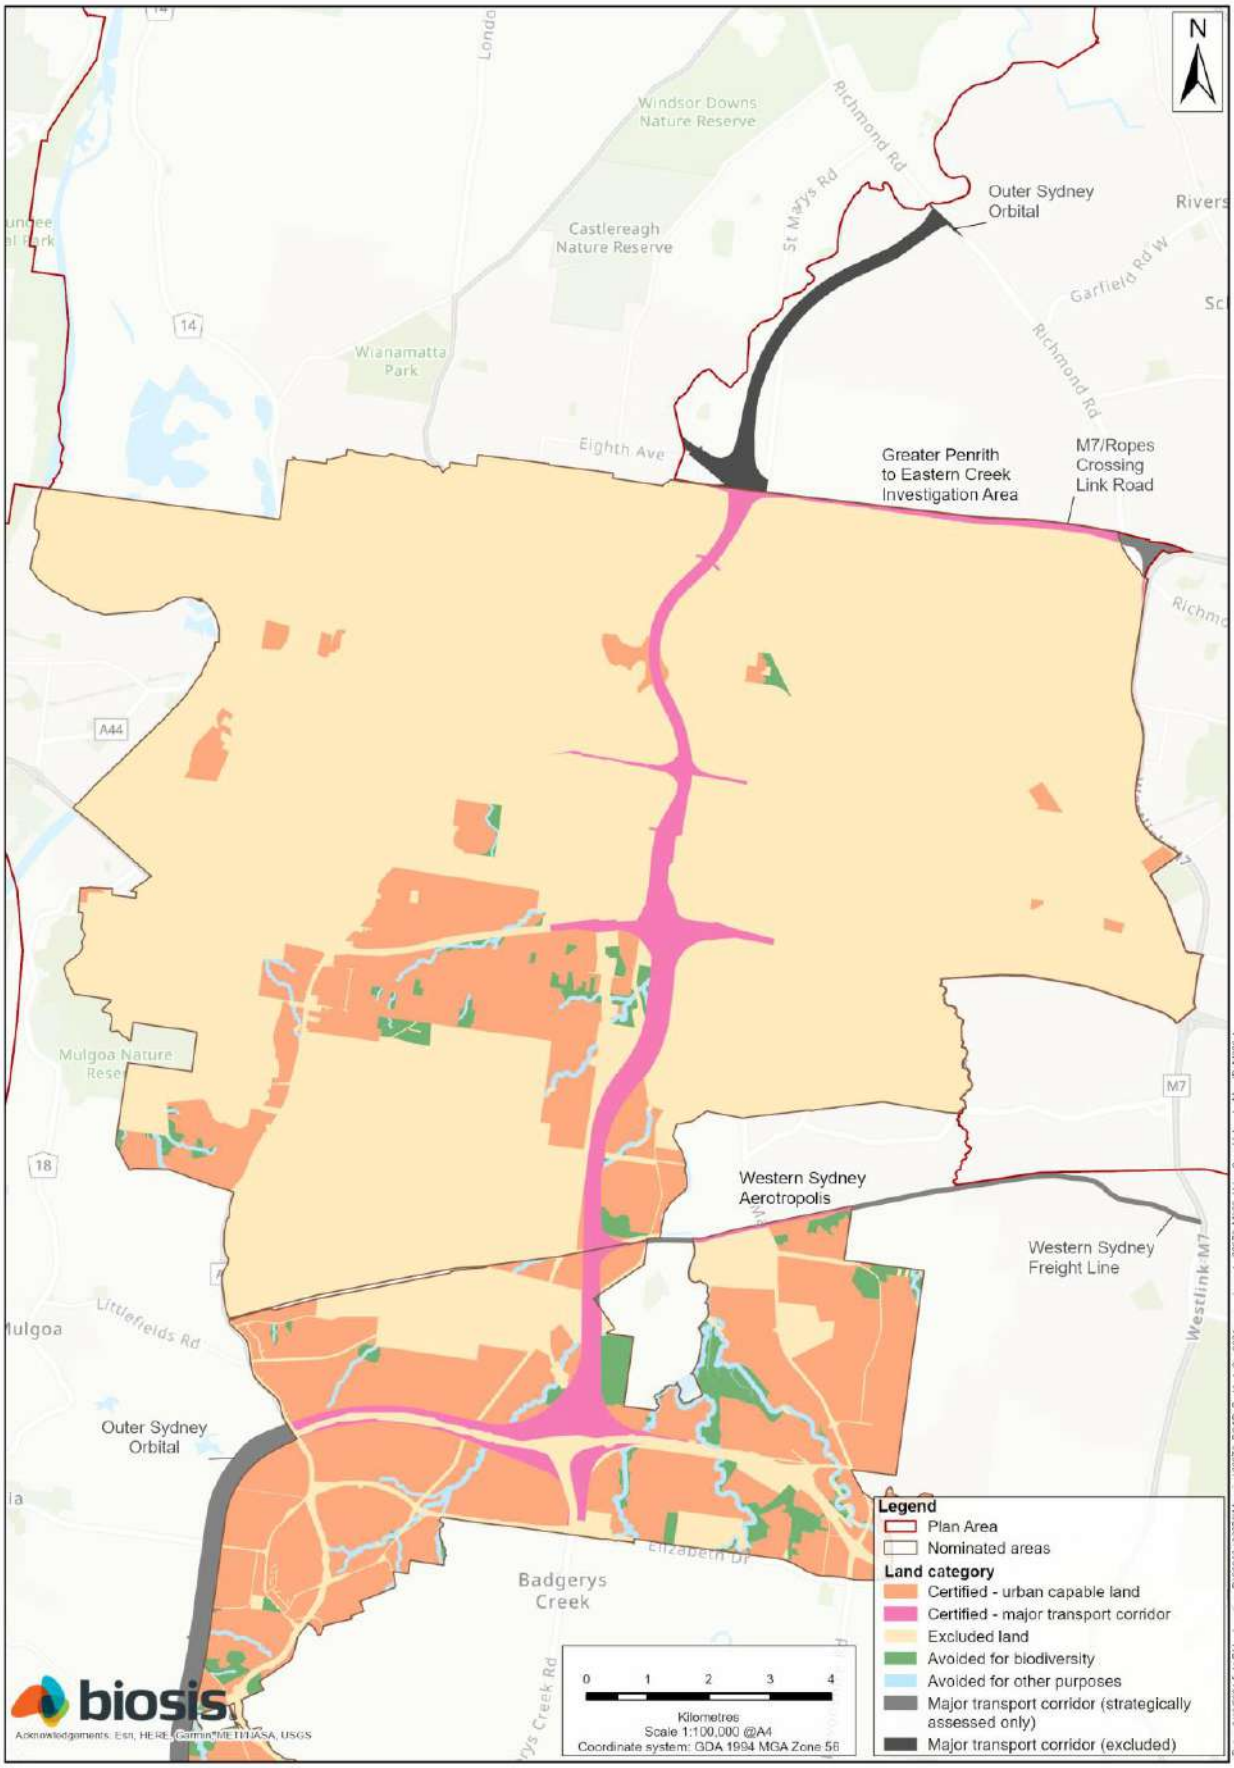

Figure 7-4: Urban capable land within GPEC

Urban and industrial development includes any development permitted through residential, business, or industrial zones, consistent with the structure plan and precinct plans for each nominated area. This includes:

- Mixed residential, commercial, and industrial development, to provide houses, jobs, services, and open and recreational spaces
- Major town centres with a full range of shops, and public and private recreational facilities and services, along with smaller village centres and neighbourhood shops
- Social infrastructure such as education facilities, cultural facilities, childcare services, sports facilities, entertainment facilities, places of public worship, libraries, and community centres
- Essential services such as health facilities and emergency services facilities
- General industrial facilities such as retail outlets, manufacturing industries, training facilities, information and technology facilities, light industries, high-tech industries, material supply centres and distribution centres
- Supporting infrastructure for parks and public reserves (environmental facility, information and education facility, kiosk, recreation area, recreation facilities (outdoor), water recreation structure)
- Agribusiness, including businesses associated with the production, processing, marketing, and distribution of agricultural products. This includes biotechnology research and development, organisations involved in smart high-tech farming practices, data centres, technical services for robotics and farm machinery, food processing, export enabling infrastructure and general administrative services
- Wholesale markets, including retail, accommodation, and large distribution centres, trading floor and associated infrastructure such as cold stores, ripening rooms, treatment facilities and waste management
- Advanced food manufacturing and logistics
- Warehouse, freight, and logistics, including distribution centres, freight transport facilities and heavy industrial storage establishments and storage premises
- Airport and ancillary uses to support the delivery and operation of the new airport

7.2.2 REQUIREMENTS UNDER THE PLAN TO MANAGE IMPACTS

The urban and industrial development will be subject to a range of requirements under the Plan to manage impacts on biodiversity values, and the Plan has introduced mechanisms to support this. This includes:

- Commitments and actions to avoid and minimise, mitigate and offsets impacts. These are provided in Attachment A
- Mitigation measures and processes to manage indirect impacts. These are described in Chapter 15, Section 15.6.1
- Planning mechanisms to support implementation. These are summarised in Chapter 9

7.3 INFRASTRUCTURE

7.3.1 DESCRIPTION OF THE DEVELOPMENT

Infrastructure development includes:

- Electricity transmission or distribution networks
- Gas pipelines
- Road or road infrastructure facilities, including public transport facilities
- Railways and rail infrastructure facilities
- Water reticulation systems, water storage facilities, water treatment facilities, or a water supply system
- Telecommunications facilities or telecommunication network
- Stormwater management system
- Resource recovery facility, waste disposal facility, waste or resource management facility and waste or resource transfer station
- Organic waste and composting facilities
- Koala exclusion fencing as described in the State Environmental Planning Policy (SEPP) (Strategic Conservation Planning)
- Fauna crossings as described in the SEPP (Strategic Conservation Planning)

Related activities and developments associated with the delivery of infrastructure under this class of action are set out in SEPP (Infrastructure) 2007. Development in this class of actions does not include activities described in the Western Sydney Major Transport Corridors class of actions.

Infrastructure development will be limited to urban capable land within the nominated areas, except for 'essential infrastructure', which may be carried out by a public authority on avoided land.

ESSENTIAL INFRASTRUCTURE

'Essential infrastructure' may be carried out by a public authority on avoided land within the nominated areas (i.e. on land outside the urban capable land, but not including excluded land), provided the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development are followed. The guidelines limit the scope of infrastructure development within these areas and ensure development avoids and mitigates and offsets any impacts to biodiversity values.

The guidelines specify a range of requirements to achieve this outcome, including that:

- The environmental impacts of the projects are considered under the EP&A Act, and where triggered, also under the BC Act in accordance with the NSW Biodiversity Assessment Method
- An 'avoid and mitigate' process is applied as part of this assessment process
- Any relevant MNES-specific requirements of the Plan are applied
- The public authority notifies the Department of the development

Essential infrastructure on avoided land will also need to meet specific Plan commitments for avoidance (Commitment 2.1 and Commitment 2.2). This includes limiting cumulative direct impacts to Commonwealth-listed TECs over the life of the Plan in accordance with specific impact thresholds.

The impacts of essential infrastructure are assessed in Chapter 37.

7.3.2 REQUIREMENTS UNDER THE PLAN TO MANAGE IMPACTS

Infrastructure will be subject to future environmental assessment and approval processes under the EP&A Act at the time the projects are proposed. Infrastructure covering the broad types under the Plan is subject to different environmental assessment processes. The SEPP (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed and approved under the EP&A Act.

Infrastructure will be subject to a range of requirements under the Plan to manage impacts on biodiversity values, and the Plan has introduced mechanisms to support this. This includes:

- Commitments and actions to avoid and minimise, mitigate and offsets impacts. These are provided in Attachment A
- Mitigation measures and processes to manage indirect impacts. These are described in Chapter 15 (Section 15.6.2)
- Planning mechanisms to support implementation. These are summarised in Chapter 9

7.4 INTENSIVE PLANT AGRICULTURE

7.4.1 DESCRIPTION OF THE DEVELOPMENT

The Western Sydney International (Nancy-Bird Walton) Airport presents an opportunity to invest in intensive plant agriculture industries. The Agribusiness Precinct within WSA occurs on the northern and western edges of the airport and supports the long-term retention and growth of intensive plant agriculture in the Western Parkland City.

Intensive plant agriculture will be confined to the Agribusiness Precinct within WSA (see Figure 7-5) and includes existing, new, and proposed agricultural areas to support the nominated areas program. While agricultural production will be confined within the Agribusiness Precinct, associated development related to agribusiness, wholesale markets, manufacturing and logistics may occur in other precincts.

Intensive plant agriculture development must satisfy and meet the relevant objectives of the National Airport Safeguarding Framework and may include:

- Intensive plant agriculture, including protective cropping structures used primarily for horticultural applications to control specific environmental conditions and facilitate high-quality, high-quantity production of a defined fruit, vegetable, or flower
- Cultivation of irrigated crops for commercial purposes (other than irrigated pasture or fodder crops)
- Horticulture
- Viticulture

7.4.2 REQUIREMENTS UNDER THE PLAN TO MANAGE IMPACTS

Intensive plant agriculture will be subject to a range of requirements under the Plan to manage impacts on biodiversity values, and the Plan has introduced mechanisms to support this. This includes:

- Commitments and actions to avoid and minimise, mitigate and offsets impacts. These are provided in Attachment A
- Mitigation measures and processes to manage indirect impacts. These are described in Chapter 15, Section 15.6.1
- Planning mechanisms to support implementation. These are summarised in Chapter 9

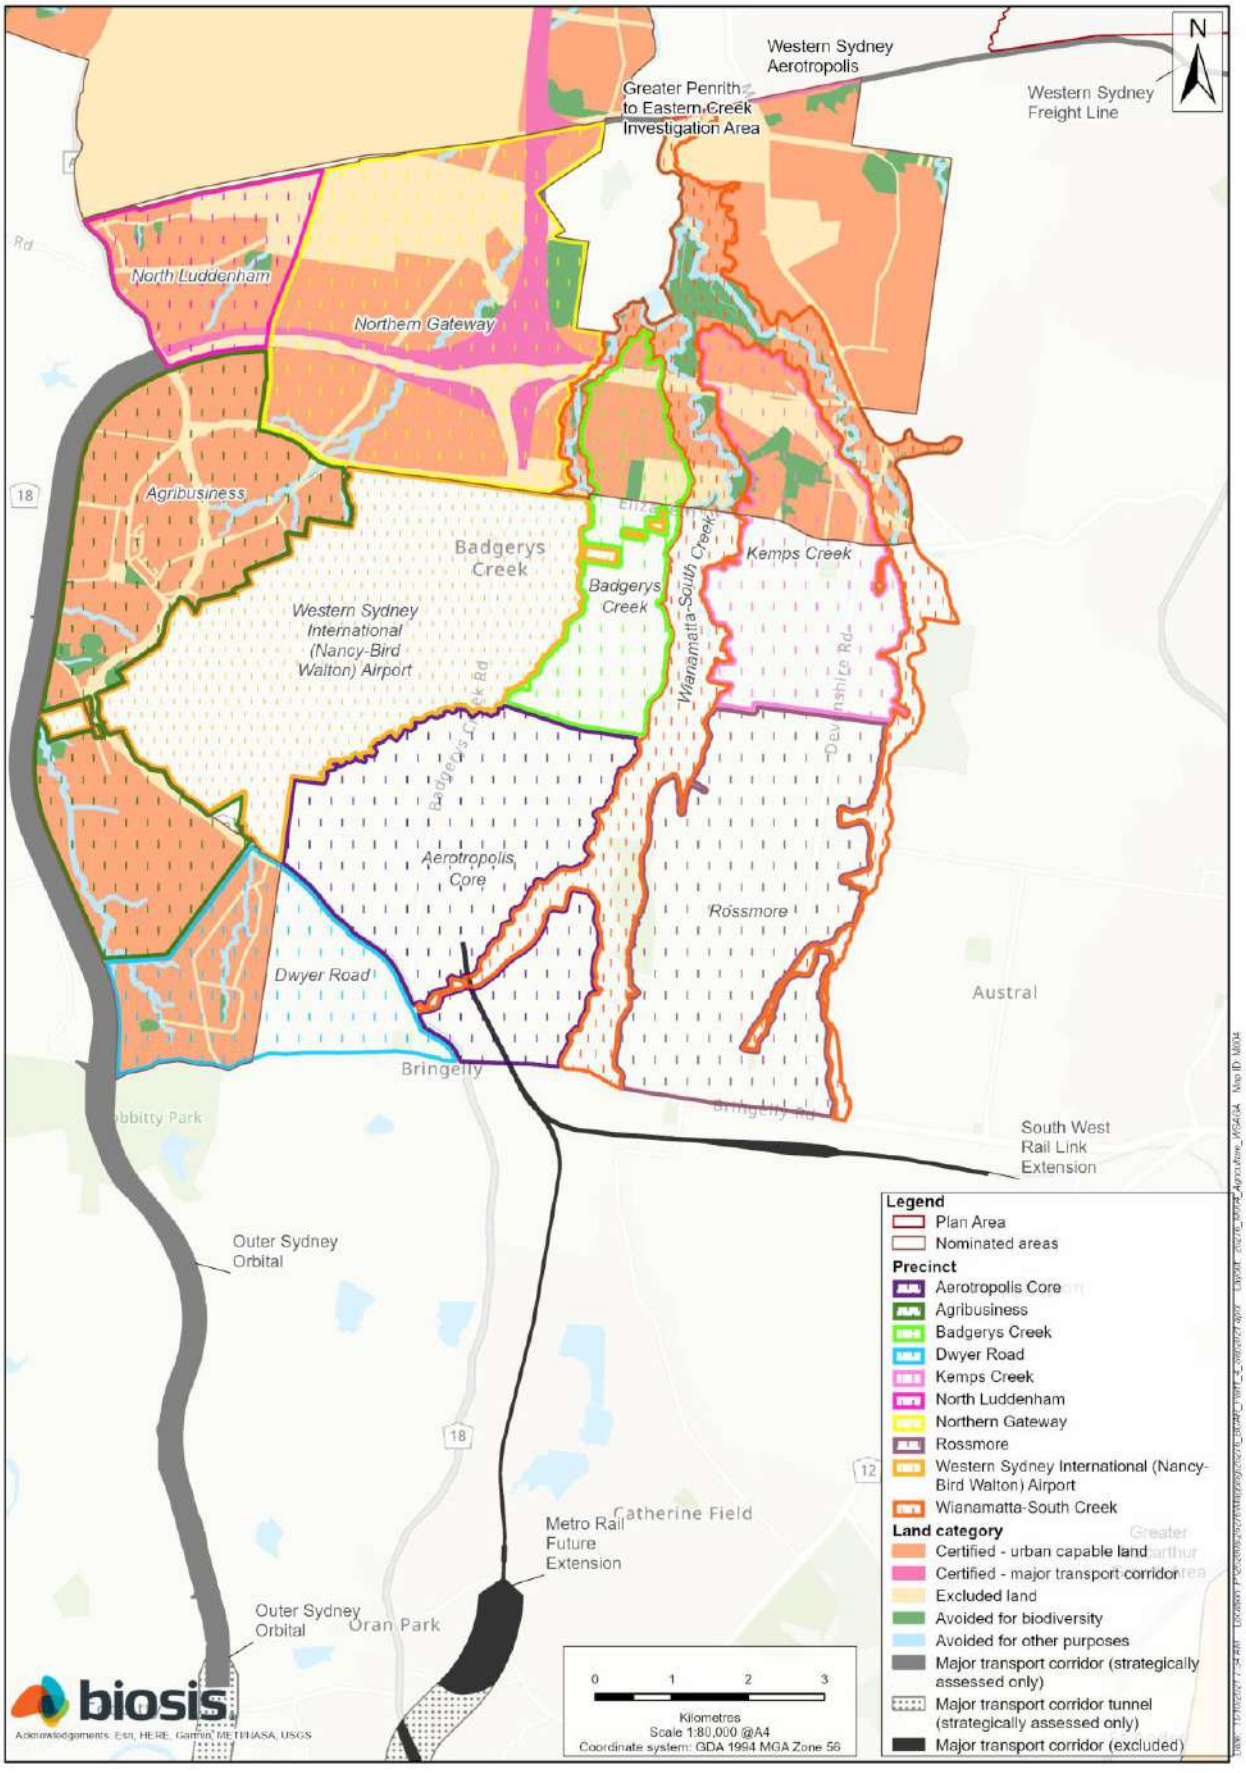

Figure 7-5: Agriculture and Agribusiness Precinct of WSA

7.5 MAJOR TRANSPORT CORRIDORS

7.5.1 DESCRIPTION OF THE DEVELOPMENT

The NSW Government is finalising long term major transport corridors for Western Sydney by identifying and protecting corridors that can be used to deliver the components of a future major transport network. These corridors will facilitate the delivery of major road and rail projects to meet the long-term needs of Western Sydney, as outlined in the *Future Transport Strategy 2056* (Transport for NSW, 2018) and the Greater Sydney Region Plan.

For Western Sydney, the major transport corridors are planned to be delivered over the next 40 years. The delivery and timing of the road and rail infrastructure within the corridors is subject to future NSW Government decisions. The responsibility for delivery of the transport infrastructure rests with Transport for NSW and Sydney Metro.

As described in Part 1, the major transport corridors are subject to different statutory approvals under the Plan and are categorised in this Assessment Report to reflect this. This is shown in Table 7-2.

Table 7-2: Major transport corridors being assessed for approval under the BC Act and the EPBC Act

Major transport corridors	Biodiversity certification under BC Act	Approval under Part 10 of EPBC Act
Within the nominated areas. These corridors are referred to as: • 'Major transport corridors – certified'	✓	✓
Outside the nominated areas. These corridors are referred to as: • 'Major transport corridors – non-certified (strategically assessed)'* • 'Major transport corridors tunnel – non-certified (strategically assessed)'^	-	✓

* Biodiversity certification may be sought for the transport corridors outside the nominated areas at a later date, and may be included as a modification or series of modifications to this biodiversity certification

^ Note that a small part of the tunnel section of the major transport corridors occurs within a nominated area (GMAC), but this is not subject to biodiversity certification under the BC Act

Table 7-3 identifies the proposed major transport corridors under the Plan, the indicative timing for investigating their delivery, their general location in the Plan area, and their approval category under the Plan.

The indicative locations of the major transport corridors are shown in Figure 7-6.

Table 7-3: Major transport corridors

Project	Description	Timing for investigation	General location	Approval categories under Plan
Metro Rail Future Extension from WSA to Macarthur (except for those areas within the existing South West Growth Area)	Provides for a future extension of the metro rail south from the Aerotropolis (Bringelly) to Macarthur	0 to 10 years	Located between Oran Park and Campbelltown	• Major transport corridors – certified • Major transport corridors – non-certified (strategically assessed) • Major transport corridors tunnel - non-certified (strategically assessed)
Western Sydney Freight Line corridor	Provides for a future freight rail line to connect Port Botany and Western Sydney	10 to 20 years	Located between Luddenham and Orchard Hills in the	• Major transport corridors – certified • Major transport corridors – non-

Project	Description	Timing for investigation	General location	Approval categories under Plan
			West and Horsley park in the east	certified (strategically assessed)
Outer Sydney Orbital between Box Hill and the Hume Motorway near Menangle	Provides for a future north-south motorway and freight rail line		Located between Ropes Crossing in the north and Douglas Park in the south	• Major transport corridors – certified • Major transport corridors – non-certified (strategically assessed) • Major transport corridors tunnel - non-certified (strategically assessed)
M7/Ropes Crossing Link Road	Provides for a future east-west motorway linking the M7 to the future Outer Sydney Orbital at Ropes Crossing	20 or more years	Located within and outside the north-east boundary of GPEC between Willmot and Dean Park	• Major transport corridors – certified • Major transport corridors – non-certified (strategically assessed)

The major transport corridors include all activities associated with the design, construction, and operation of the major road or rail projects. Infrastructure development will generally occur within the major transport corridors shown in the Plan (see Figure 7-6) although in some cases, development may be necessary adjacent to the corridor.

The transport activities included under the Plan include, but are not limited to:

- Vegetation clearing
- Earthworks
- Utility works
- Landscaping
- Erosion and sediment control
- Laydown areas
- Road and rail construction and operation
- Tunnel construction and operation
- Construction of supporting infrastructure such as stations, car parks and pedestrian access
- Electricity infrastructure
- Site offices and access roads
- Dust and noise suppression
- Stormwater management (including detention basins, ponds and dams)
- Vehicle and train movements
- Maintenance and upgrade activities
- Installation and maintenance of traffic control and safety infrastructure

Local, state, or regional distributor roads that feed from and to the major transport corridors are not part of the major transport corridor program and will be established as part of the infrastructure class of action (local roads) or via separate planning processes (state, classified or regional roads).

It is important to note that sections of a number of the major transport corridors occur within the existing North West and South West Growth Areas. These sections already have EPBC Act approval under the previous Part 10 strategic assessment for the growth areas and are therefore not further considered in this Assessment Report.

TUNNELS

The major transport corridors include the construction and operation of tunnels. Sections of two of the major transport corridors are proposed to include tunnels. These are:

- Outer Sydney Orbital – Cobbitty to Cawdor
- Metro Rail Future Extension tunnel – Oran Park to Narellan, and Narellan to Macarthur

The locations of the tunnels are shown in Figure 7-6.

7.5.2 REQUIREMENTS UNDER THE PLAN TO MANAGE IMPACTS

As each transport project is brought forward for investigation, the project will be subject to future environmental assessment and approval processes under the EP&A Act and/or the BC Act. The assessment process will depend on whether the project is proposed for certification under the Plan:

- For the 'major transport corridors – certified', the environmental assessment process will comprise the State Significant Infrastructure (SSI) (or equivalent) assessment process under the EP&A Act
- For the 'major transport corridors – non-certified (strategically assessed)' and 'major transport corridors tunnel - non-certified (strategically assessed)', the environmental assessment process will comprise both the SSI (or equivalent) and the BC Act and BAM (or equivalent) assessment processes

The major transport corridors will also be subject to a range of requirements under the Plan to manage impacts on biodiversity values and mechanisms to support this. This includes:

- Commitments and actions to avoid and minimise, mitigate and offsets impacts. These are provided in Attachment A
- Mitigation measures and processes to manage indirect impacts. These are described in Chapter 15 (Section 15.6.3)

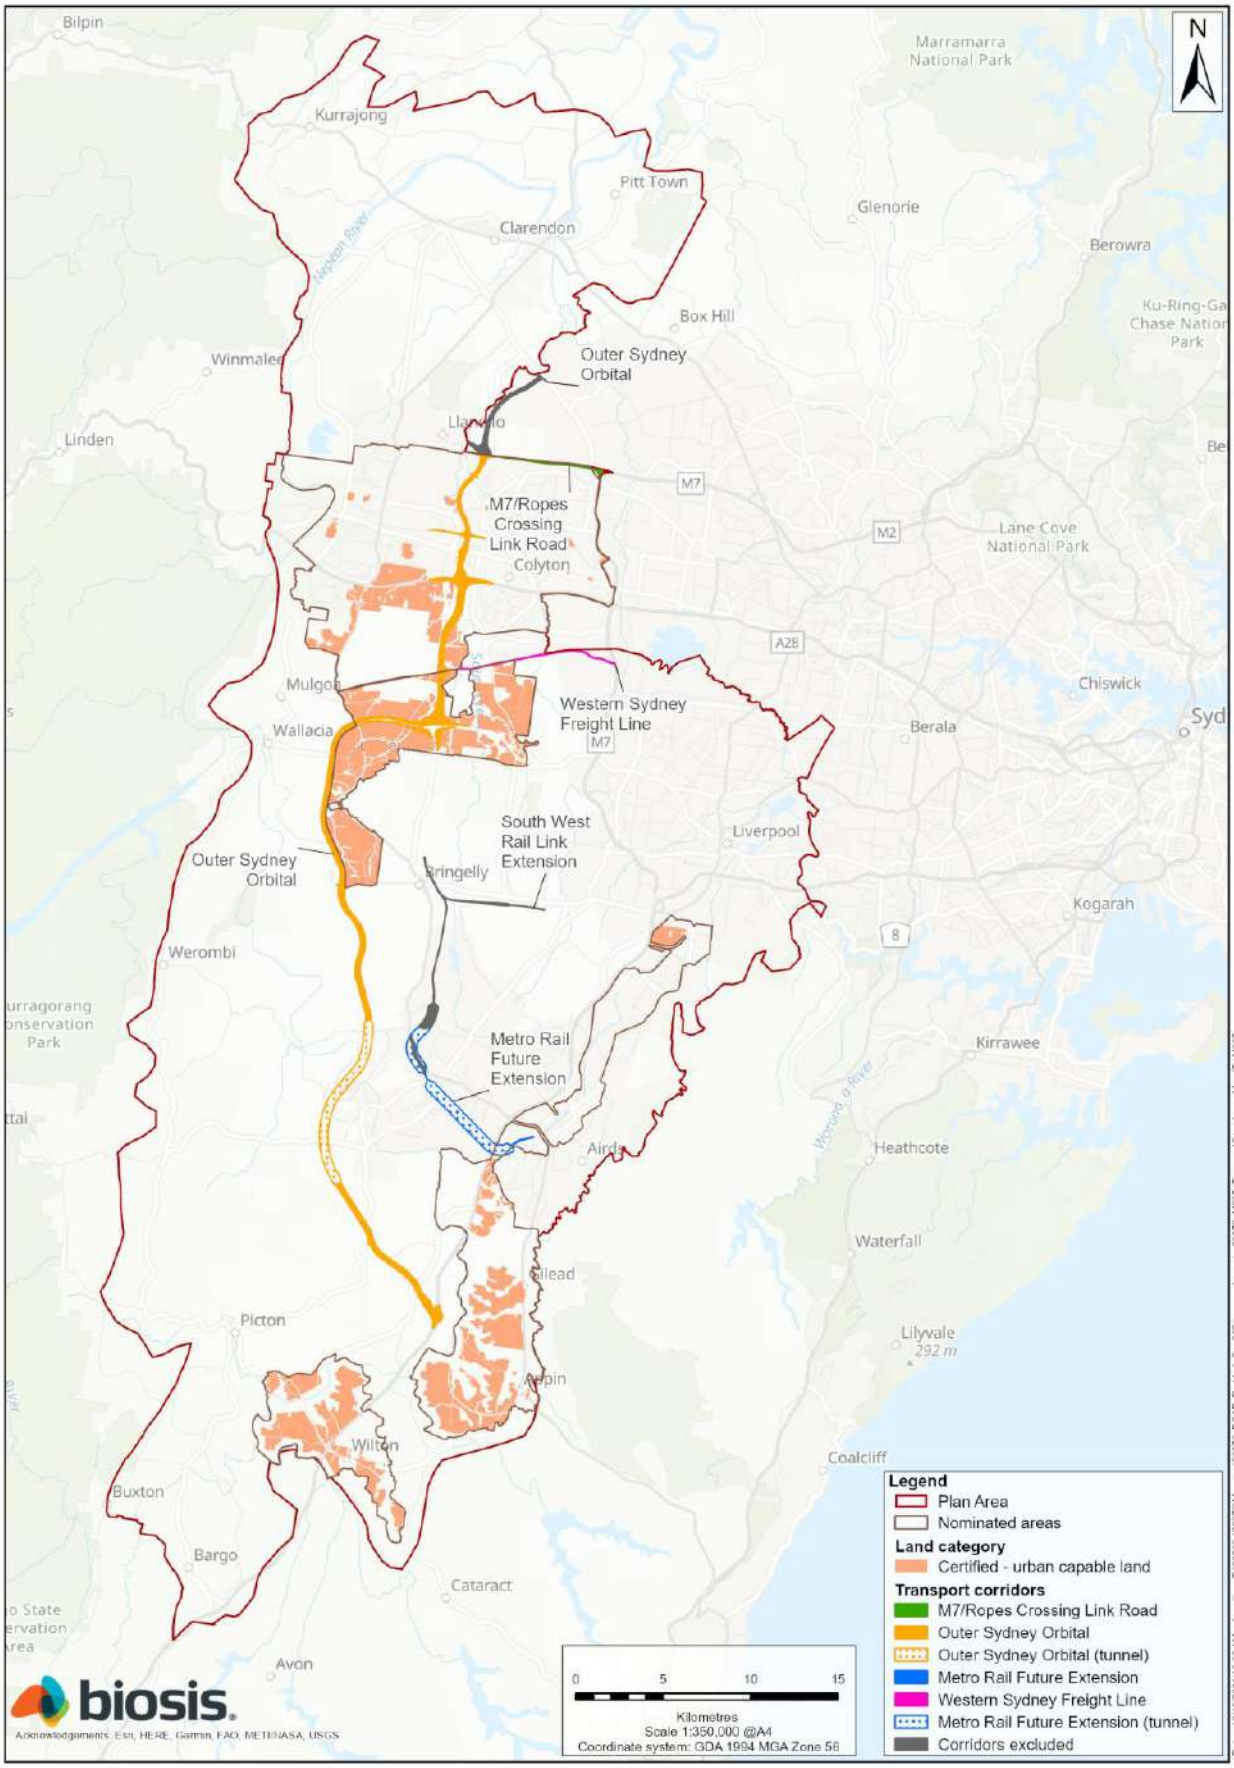

Figure 7-6: Indicative locations of major transport corridors

8 Conservation program of the Plan

8.1 INTRODUCTION

The Plan includes a conservation program to avoid and minimise, mitigate, and offset direct, indirect and prescribed impacts of the development under the Plan on biodiversity values and other protected matters.

This Chapter describes the conservation program under the Plan, including:

- Overview of the conservation program
- Commitments and actions to deliver the conservation program
- Koala conservation program
- Development of the conservation program

The conservation program and commitments and actions associated with the program are supported by a range of implementation mechanisms to ensure its delivery. These are summarised in Chapter 9.

Part 7 provides an evaluation of the adequacy of conservation program in addressing the impacts of the development.

8.2 OVERVIEW OF THE CONSERVATION PROGRAM

8.2.1 PURPOSE OF THE CONSERVATION PROGRAM

The purpose of the conservation program is to achieve the Plan's objective and conservation outcomes and avoid, mitigate, and offset the direct, indirect, and prescribed impacts of the development under the Plan on biodiversity values.

The NSW Government has committed $114 million to fund the conservation program and deliver priority conservation actions over the first five years of implementation. The priority conservation actions include:

- Purchasing land to establish new reserves including the Georges River Koala Reserve
- Commencing restoration of koala habitat including installation of Koala crossings and predator exclusion fences
- Supporting the NSW Koala Strategy including the commencement of annual monitoring in the region
- Establishing partnerships including with the Biodiversity Conservation Trust to facilitate formation of biodiversity stewardship agreements; primarily in the Razorback Area which is dominated by Cumberland Plain Woodland
- Partnering with the NSW Aboriginal Land Council to establish a grant program for Western Sydney Local Aboriginal Land Councils to deliver cultural and conservation opportunities

These actions are detailed further in section 8.3 in relation to key elements of the conservation program (see below).

8.2.2 KEY ELEMENTS OF THE CONSERVATION PROGRAM

The key elements of the conservation program are:

1. Avoiding and minimising impacts
2. Mitigating indirect and prescribed impacts
3. Conserving flora, fauna, and habitat
4. Managing landscape threats
5. Building knowledge and capacity

Each of these elements are discussed in Section 8.3.

The key focus of the conservation program is conserving flora and fauna and habitat by securing priority conservation areas in the Cumberland subregion to offset the impacts of the development under the Plan on biodiversity values and maximise ecological function and resilience at the landscape scale.

8.2.3 OUTCOMES

The outcomes of the Plan deliver the Plan's vision and objective. They include economic, social and environmental outcomes. The environmental outcomes of the Plan are:

> *The extent and condition of native vegetation and Threatened Ecological Communities increases and improves in the strategic conservation area in the Cumberland subregion*
>
> *Populations of targeted threatened species persist, and the condition of suitable habitat improves in the strategic conservation area in the Cumberland subregion*
>
> *Condition of important koala habitat is improved, connectivity between koala sub-populations is maintained, threats to koalas are managed and the koala population in South Western Sydney persists and thrives*
>
> *Areas of high biodiversity value in the nominated areas are protected and threats to species and ecological communities from increased urbanisation is managed*

8.2.4 COMMITMENTS

Commitments are what will be done to deliver the Plan's outcomes. The Plan includes commitments relating to each element of the conservation program. The commitments will be implemented over the life of the Plan.

8.2.5 ACTIONS

Actions are what will be done to deliver the commitments. Each commitment has a set of actions associated with it. Actions are set out in the Sub-Plans and may be subject to change following approval of the Plan.

8.3 COMMITMENTS AND ACTIONS TO DELIVER THE CONSERVATION PROGRAM

This Section provides a summary of the key commitments and actions to deliver the conservation program. The commitments and actions are identified under the five key elements of the conservation program. The full list of commitments and actions in the Plan, including timing for implementation, are provided in Attachment A.

8.3.1 AVOIDING AND MINIMISING IMPACTS

The Plan includes a commitment (Commitment 2) to avoid and minimise impacts from urban and industrial and infrastructure development to at least 4,505 hectares of high biodiversity value area through strategic planning of the nominated areas. This commitment will be delivered through several actions, including:

- Introducing an Environmental Planning Instrument (EPI) to apply development protect important biodiversity on avoided land under the Plan (this EPI is a State Environmental Planning Policy and is described in Section 9.2.1)
- Prepare a Ministerial Direction under section 9.1 of the EP&A Act to require planning proposals by planning authorities to protect or enhance and/or minimise impacts to biodiversity values and to prevent planning authorities from rezoning avoided land for development-related land-uses
- Introducing the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development to manage impacts on biodiversity from infrastructure, including essential infrastructure, on avoided land in the nominated areas
- Monitoring the impacts of development on avoided land through the Plan's reconciliation accounting process
- Notifying proponents of essential infrastructure of their obligations under the EPBC Act, including when development does not have Part 10 EPBC Act approval under the Plan
- Locating asset protection zones wholly within urban capable land

Commitment 2 includes limiting the cumulative direct impacts from essential infrastructure on avoided land for six Commonwealth listed TECs to identified impact thresholds (Commitment 2.1) and prioritising avoidance of known populations of specific flora species and important Koala corridors (Commitment 2.2).

The Plan also includes commitments (Commitment 3 and Commitment 4) for further avoidance and minimisation in relation to the major transport corridors, including the tunnel sections of the corridors.

Note development controls in the SEPP (Strategic Conservation Planning) will not apply to avoided land that is owned or under claim by LALCs.

8.3.2 MITIGATING INDIRECT AND PRESCRIBED IMPACTS

The Plan includes several commitments (Commitment 5, Commitment 6, and Commitment 7) related to mitigating indirect and prescribed impacts. These include to mitigate indirect and prescribed impacts from:

- Urban and industrial development, infrastructure, and intensive plant agriculture on TECs, species and their habitat in accordance with the mitigation measures in Appendix E of the Plan
- Major transport corridors on TECs, species and their habitat in accordance with NSW SSI (or equivalent) approval process and/or BAM process and the mitigation measures in Appendix E of the Plan
- Urban and industrial development, infrastructure, and major transport corridors on the Southern Sydney Koala population to best practice standards and in line with the recommendations of the Office of the NSW Chief Scientist & Engineer and Appendix E of the Plan

Sub-plan A identifies several actions to deliver these commitments, including:

- Incorporating development controls in State-led development control plans for each nominated area setting out development controls that need to be addressed by neighbourhood plans and development applications to mitigate indirect and prescribed impacts on threatened species.
- For the major transport corridors, implementing specific mitigation measures prescribed in Appendix E and identifying and implementing additional mitigation measures based on the outcomes of future environmental assessments in accordance with the requirements of the SSI (or equivalent) approval process
- A range of mitigation measures for Koala, including:
    - Constructing exclusion fencing between important Koala habitat and urban capable land in Wilton and GMAC and several other locations, including the western alignment of the Georges River Koala Reserve
    - Providing safe fauna crossings across Appin Road

8.3.3 CONSERVING FLORA AND FAUNA AND HABITAT

This category of commitments is the key focus of the conservation program. The key commitment of the Plan (Commitment 8) to offset the impacts of the development on biodiversity values is to protect a minimum of 5,325 hectares of native vegetation in the Cumberland subregion to conserve biodiversity values in perpetuity.

As part of this commitment, the Plan will:

- Protect specific minimum amounts of Commonwealth and NSW-listed TECs (Commitments 8.1 and 8.2)
- Protect populations of species considered at risk of residual adverse impacts from the development (Commitment 9)
- Establish a Georges River Koala Reserve to protect a Koala movement corridor along the Georges River (Commitment 10)
- Establish at least two new reserves in addition to the Georges River Koala Reserve to protect TECs and species habitat that are targeted for protection under the Plan (Commitment 11)
- Secure key koala habitat corridors in the Cumberland subregion in perpetuity (Commitment 12)
- Undertake ecological restoration of up to 25% of the Plan's offset target for native vegetation in conservation land established under the Plan (Commitment 13)
- Minimise impacts from development in the Strategic Conservation Area (Commitment 14)

PRIORITY AREAS FOR CONSERVATION (STRATEGIC CONSERVATION AREA)

The Department has identified a Strategic Conservation Area (SCA) within the Cumberland subregion (comprising approximately 27,200 hectares of land within the Plan area) within which the commitment to secure 5,325 hectares of native vegetation and offset the impacts of the development under the Plan will be prioritised. It is anticipated that around 11,500 hectares, or approximately double the Plan's offset commitment of impacted native vegetation will be added to the conservation land network under the Plan. The SCA is shown in Figure 8-1.

The SCA represents the areas in the Cumberland subregion containing habitat for biodiversity values impacted by the development that are considered most likely to be viable in the long-term and maximise ecological function and connectivity across the landscape.

The SCA was identified through a Conservation Priorities Method. The method is described in Section 8.4.1. The method will be reapplied every 5 years and the SCA will be updated as required over the life of the Plan using up to date information on biodiversity values, constraints, and opportunities.

A program of ground-truthing will be undertaken to confirm the biodiversity values of the SCA consisting of desktop and aerial assessment (using satellite imagery) and on-ground surveys.

The Department has developed several approaches to establish conservation lands as offsets within the SCA over the life of the Plan to 2056. These are:

- A series of principles and steps to guide the selection of conservation lands ('Conservation Land Selection Steps')
- A reconciliation accounting process to reconcile offsets acquired through the Plan with development impacts

The Conservation Land Selection Steps allows conservation lands/offsets to be secured in cascading order, from the Cumberland subregion and adjacent subregions as a first preference, to the Sydney Basin bioregion as a second preference, to anywhere in NSW as a last resort, where the preferred options are unable to be achieved.

Offsets secured outside the Cumberland subregion are limited to 20 per cent of the offset target for native vegetation.

In some cases, offset sites may be selected from outside the SCA, but within the Cumberland subregion as a first step. This could include, for example, the purchase of biodiversity credits from existing biodiversity stewardship sites if those areas are contiguous with the SCA and would otherwise meet the criteria for a priority area.

The Department will also develop a Conservation Lands Implementation Strategy that will include:

- Priorities for selecting and purchasing conservation land
- Targets and proposed timeframes for establishing new conservation land
- Proposed land-based conservation type for each area of priority conservation land
- Suitable land managers for each area of priority conservation land
- A process to secure alternative areas where targets and timing cannot be met

MECHANISMS TO SECURE CONSERVATION LAND

Land will be secured for conservation in perpetuity through two programs:

- A reserve program to create reserves through acquisition of land
- A Biodiversity Stewardship Agreement (BSA) program to establish BSAs with landholders

The Department may also seek to purchase biodiversity credits from landholders who have already established BSAs to help deliver the offset targets, particularly the species offset targets.

Reserves

Reserves provide the highest level of in-perpetuity biodiversity protection and a range of social benefits not provided by the other commitments, such as public access to natural areas and open space.

There are a range of reserve types proposed under the Plan, including: National Park, Nature Reserve, State Conservation Area, Regional Park, Council reserve, and community-based reserves. Reserve managers will depend on the type of reserve and will be determined during implementation of the Plan.

Office of Strategic Lands (OSL) will be responsible for securing land for reserves. Land may be secured through:

- Market purchase (a voluntary negotiated sale with the landholder)
- Active acquisition (where OSL actively engage with the landowner to voluntarily purchase their land)
- Acquisition by agreement (where OSL negotiates sale of land identified for acquisition within the landholder through an agreement process and within certain timeframes)

- Compulsory acquisition in limited circumstances

The Department has identified initial locations for land that will be potentially reserved under the *National Parks and Wildlife Act 1974* (NP&W Act) within the SCA. The Georges River Koala Reserve has been announced as a priority, with the first stage (Stage 1A) to be gazetted as a reserve under the NP&W Act by year two of the Plan's implementation. Two additional priority reserves are under investigation for feasibility:

- The Gulguer Reserve Investigation Area
- The Confluence Reserve Investigation Area

These reserve locations are not final and are likely to be refined. Other areas within the SCA have also been identified for further investigation as future reserves to provide greater landscape connectivity.

Biodiversity Stewardship Agreements

BSAs will be a primary mechanism to protect conservation land under the conservation program.

BSAs are voluntary cooperative agreements between a private landholder and the NSW Government. BSAs are registered on the title of a property to provide in-perpetuity protection of biodiversity values. Landholders are responsible to ongoing management of the land using funding provided via developers.

The Biodiversity Conservation Trust (BCT) will be responsible for overseeing the delivery of the BSA program under the Plan and for ensuring compliance with the requirements of BSAs.

Due to the impacts of the development on Cumberland Plain Woodland, the NSW Government has committed to specifically investigating areas for the protection of this TEC through BSAs in the Razorback Area, which contains significant amounts of Cumberland Plain Woodland in addition to other TECs targeted for offsets under the Plan.

The conservation program will also include direct purchase of biodiversity credits from BSAs not established under the Plan, where those sites meet the selection steps and offset requirements as set out in the Plan.

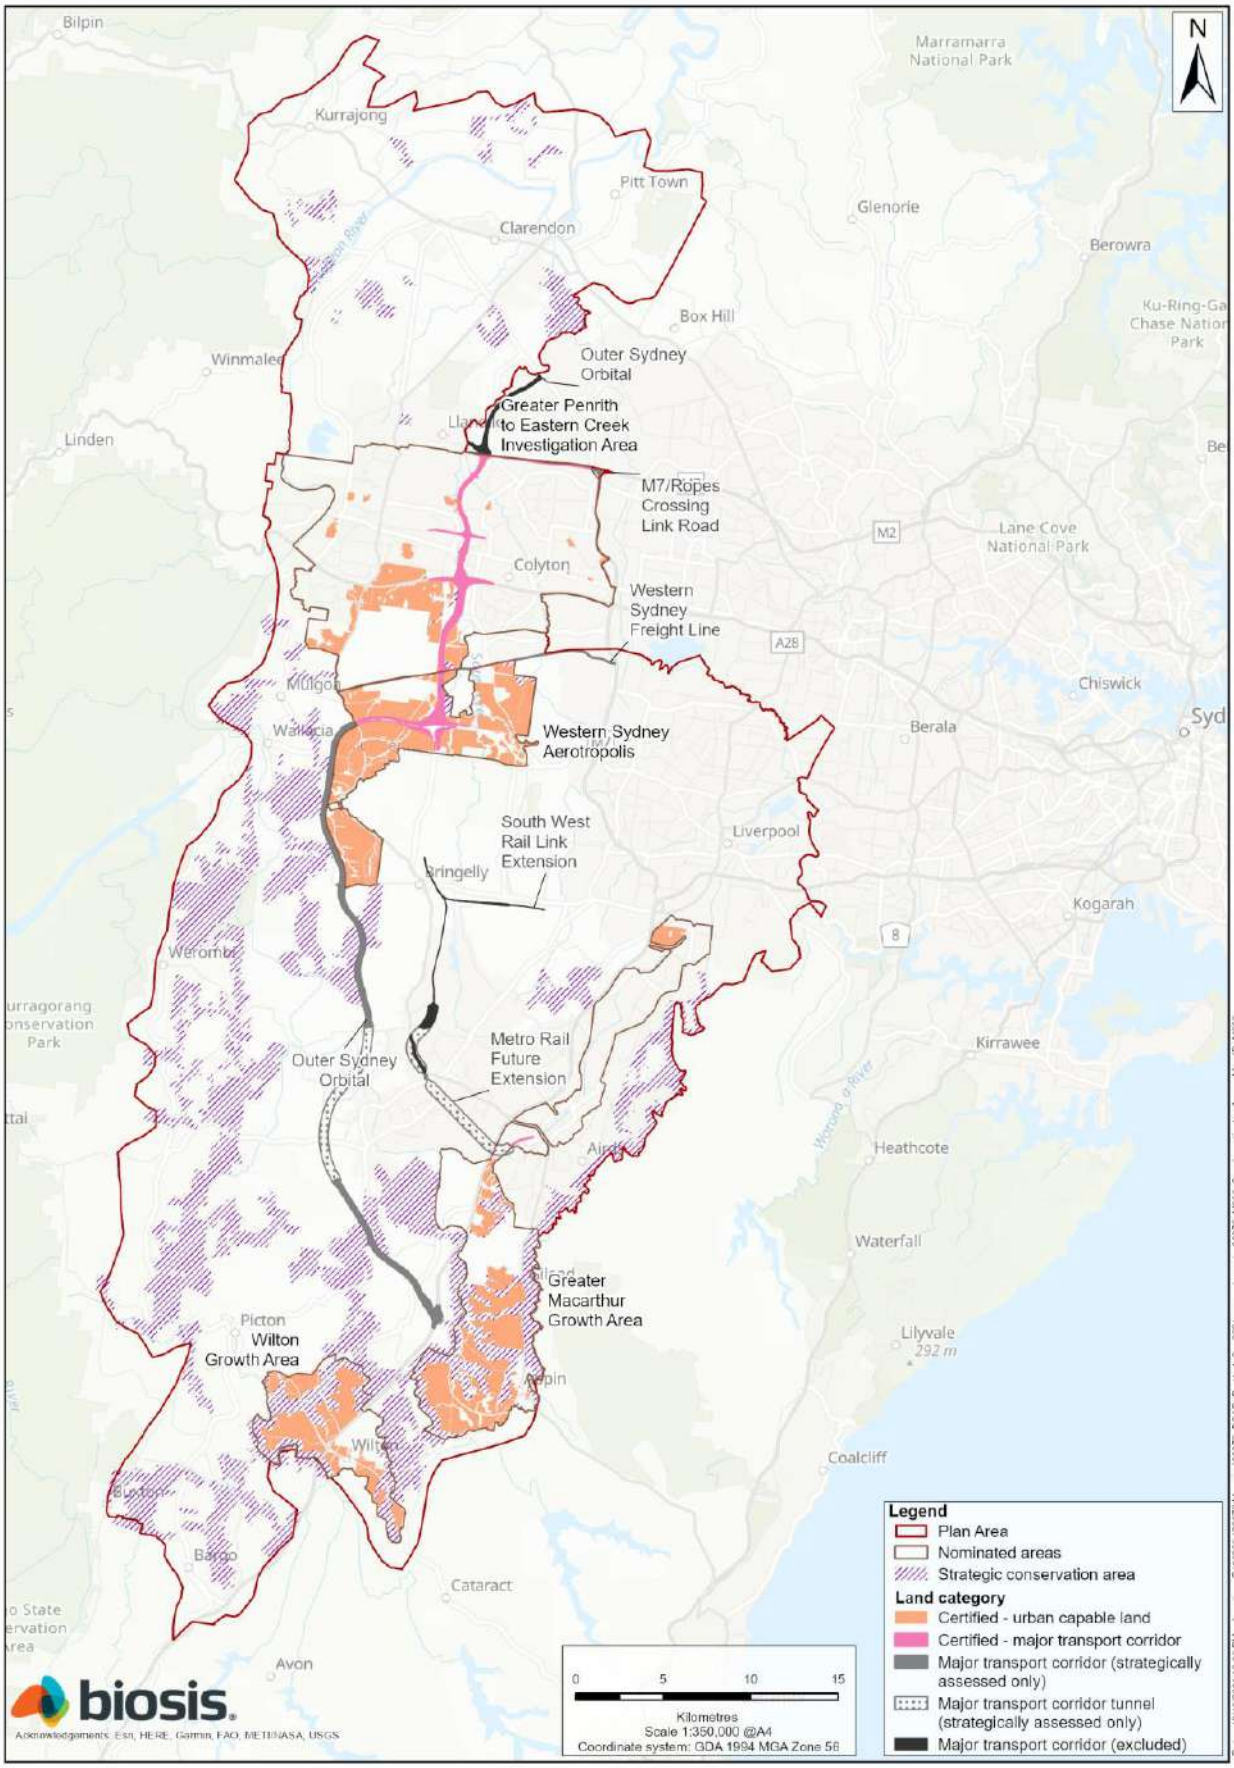

Figure 8-1: Location of Strategic Conservation Areas

RESTORATION OF LAND

As part of the commitments to secure 5,325 hectares of native vegetation (Commitment 8) and undertake ecological restoration of priority areas (Commitment 13), there is a target to restore up to 25 per cent of the offset target for native vegetation through the ecological restoration of land. A key action to deliver this target includes developing a Restoration Implementation Strategy in consultation with key delivery partners to guide restoration priorities.

Restoration efforts will focus on:

- Target TECs where there is a shortfall in established conservation land
- Expanding the habitat area for targeted threatened species
- Enhancing connectivity with reserves and neighbouring areas of high biodiversity value.

Ecological restoration works are intended to be carried out early in the life of the Plan to maximise conservation benefits. Restoration on BSA sites will be overseen by the BCT and undertaken in accordance with BCT guidelines.

INTERIM PROTECTION OF CONSERVATION LAND

The Plan includes a commitment to minimise impacts to biodiversity values on land within the SCA prior to securing land for conservation/offsets (Commitment 14). To achieve this, the Department will:

- Introduce an Environmental Planning Instrument (EPI) to apply development controls to land within the SCA to require consideration of impacts on biodiversity values when consent authorities assess development applications (this EPI is a State Environmental Planning Policy and is described in Section 9.2.1)
- Prepare a Ministerial Direction under section 9.1 of the EP&A Act to require planning proposals by planning authorities to protect or enhance and/or minimise impacts to biodiversity values and to prevent planning authorities from rezoning the SCA for development-related land-uses
- Work with local councils to integrate mapping of the strategic conservation area into local and regional planning through Local Strategic Planning Statements, which guide the local plan-making process

Note development controls in the SEPP (Strategic Conservation Planning) will not apply to land that is owned or under claim by LALCs in the SCA.

EES has provided in-principle support for including the vegetation mapped in the SCA in the Biodiversity Values (BV) map (where the vegetation is not already identified on the map). The BV map is prepared by the Department under Part 7 of the BC Act and identifies land with high biodiversity value that is sensitive to impacts from development and clearing. The map is one of the triggers for determining whether the Biodiversity Offsets Scheme applies to a proposal.

Including the vegetation mapped in the SCA in the BV map will provide additional protection for the SCA from future developments. It ensures proposals for development in the SCA that involve clearing or would result in a prescribed impact are avoided and minimised and subject to assessment and approval under the BC Act.

8.3.4 MANAGING LANDSCAPE THREATS

The Plan includes a range of commitments to manage threats to biodiversity in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA, including:

- Deliver weed and pest control programs (Commitment 15 and Commitment 16) to manage weeds and pests in strategic locations in the Cumberland subregion to reduce threats to conservation lands under the Plan
- Fire management in strategic locations (Commitment 17) to support the maintenance of biodiversity values in conservation lands under the Plan
- Support new or existing disease control programs (Commitment 18) to better manage disease affecting threatened species and TECs within the Cumberland subregion
- Support new or existing programs to help threatened species and TECs adapt to climate change (Commitment 19)

Actions under these commitments include to:

- Establish a working group on pest animals and participate in the Sydney Weeds Network to advise on threat management

- Develop more detailed implementation strategies for weeds and pests and fire in consultation with the working groups and other key stakeholders, including delivery partners, to set out:
  - Priorities for management of the threat
  - Guidance on management approaches
  - Any research needs
  - Delivery arrangements, including the provision of funding under the Plan

The Plan identifies a range of delivery partners to support implementation of these commitments and actions.

8.3.5 BUILDING KNOWLEDGE AND CAPACITY

The Plan includes a range of commitments and actions to build capacity and support stakeholders in relation to biodiversity conservation in the Cumberland subregion, including:

- Providing opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation, including Koala conservation (Commitment 20)
- Partner with Aboriginal communities in Western Sydney to deliver biodiversity conservation and support economic opportunities arising from the delivery of the Plan (Commitment 21)
- Investing in research that will support implementation of the Plan and help deliver its outcomes (Commitment 22)
- Supporting rehabilitation measures to help maintain Koala health and welfare (Commitment 23)

The Plan identifies a range of delivery partners to support implementation of these commitments and actions.

8.4 KOALA CONSERVATION PROGRAM

The Koala is one of Australia's most iconic species and the Plan includes a specific set of commitments, actions and measures to ensure the long-term protection of Koala in the Cumberland subregion.

A key commitment for Koala is to establish a reserve to secure a Koala movement corridor along the Georges River (Commitment 10) between Appin and Kentlyn. The Georges River Koala Reserve will be secured in stages, and overall will protect up to 1,830 ha of existing Koala habitat and enhance the connectivity of fragmented patches of Koala habitat through restoration.

The Plan also includes a commitment to protect Koala corridors in the Cumberland subregion (Commitment 12). Actions under this commitment relevant to Koala include:

- Protecting avoided Koala habitat through the application of new development controls in potential east-west Koala movement corridors between the Georges River and the Nepean River
- Restoring Koala habitat in the Georges River and Ouesdale Creek corridors to ensure they meet requirements for safe and functional Koala movement corridors, consistent with the advice from the Office of the NSW Chief Scientist & Engineer
- Perimeter fencing east-west Koala corridors which are too narrow to support safe passage of Koalas through the landscape

Commitment 7 is also a key commitment relating to Koalas and relates to protecting Koalas from indirect and prescribed impacts under the Plan. Key actions include:

- Installing Koala exclusion fencing between important koala habitat and urban capable land within GMAC and Wilton, or where fencing is not feasible, installing additional controls to protect Koalas
- Installing exclusion fencing along both sides of Appin Road to mitigate the threat of road mortality for Koalas
- Managing the threat to Koalas posed by dogs on all public land identified as important Koala habitat
- Providing safe fauna crossings across Appin Road and other linear infrastructure, including:
  - An underpass at Brian Road
  - Augmenting the existing Kings Fall Bridge at George River to enable Koala passage
  - Investigating options for enhancing Koala movement across the Upper Canal

Appendix E of the Plan also outlines a range of species-specific measures which will be implemented to protect Koalas from indirect and prescribed impacts from development.

The Plan also includes commitments or actions to:

- Undertake ecological restoration to improve Koala habitat quality and connectivity (Commitment 13)
- Establish research programs for the Southern Sydney Koala population (Commitment 22)
- Investing in the NSW Koala Strategy (OEH, 2018) (under Commitments 20 and 23) to:
    - To implement the Koala health and welfare program in South Western Sydney
    - Raise awareness of the Southern Sydney Koala population

Koala movement corridors are shown in Figure 8-2.

Further details on the Koala conservation program are provided in Sub-Plan B.

8.4.1 DEVELOPMENT OF THE CONSERVATION PROGRAM

The conservation program was informed by two key processes to identify priority areas for conservation and establish offset targets that will adequately offset the impacts of the development on biodiversity values.

- A method to identify the SCA (called the Conservation Priorities Method)
- Establishment of offset targets

8.4.2 CONSERVATION PRIORITIES METHOD

The SCA was identified through a Conservation Priorities Method. The method combines detailed spatial information about biodiversity values with an analysis of constraints and opportunities to identify an optimal mix of potential conservation sites to offset the impacts of the development on biodiversity values.

The method builds on the significant amount of strategic conservation planning that has occurred in the Cumberland subregion over the last decade, including the Cumberland Plain Recovery Plan (DECCW, 2011) and Biodiversity Investment Opportunities Map (OEH, 2015).

The method is summarised in Box 2 (taken from Sub-Plan A).

Box 2: Summary of Conservation Priorities Method

The Method uses multi-criteria analysis to achieve a ranking of conservation priorities, using three stages:

Stage 1 – Ecological assessment model

The first stage identifies the areas of highest biodiversity value based on an ecological assessment of remaining vegetation patches and their proximity to key features and applying a set of criteria that would either constrain or permit that area to be used as an offset

Thresholds for the minimum area of offset required for each target Plant Community Type (PCT) were identified based on impact, predicted offset required and the amount of each PCT remaining in the landscape after the application of phase '0' constraints

Offset requirements were determined by applying a matrix that applies an offset ratio to all impacted entities based on their conservation status and condition. In accordance with the matrix, the offset ratio increases both as conservation significance increases and as the condition of vegetation improves

Phase 2 – Constraints assessment model

The remaining vegetation and species habitat available for potential offset is assessed for further constraints that could challenge the implementation of commitments

Stage 3 - Conservation priorities assessment & offset selection method

This stage identifies suitable conservation areas based on Stages 1 and 2 using vegetation and species offset selection methods (noting that the selection of suitable offset areas is done from the ground up', i.e. from PCT and threatened species habitat to the landscape scale)

Stage 4 – Ground-truthing program

The final stage confirms the offset selections using a detailed desktop assessment and an 'over-the-fence' style assessment of specific sites, where observations are generally made at some distance from the property. This is conducted by a BAM-accredited assessor, collecting ecological data using a fit-for-purpose Rapid Assessment Method (RAM) digital form. This stage allows for the vegetation mapping to be updated and offset boundaries adjusted based on the results of the ground-truthing program.

8.4.3 DEVELOPMENT OF OFFSET TARGETS

The conservation program includes commitments to protect 5,325 hectares of native vegetation in conservation lands. As part of this commitment, the Plan establishes offset targets for specific biodiversity values to ensure that the commitment addresses the biodiversity values being impacted. Offset targets have been developed for:

- Each impacted Commonwealth-listed TEC
- Each impacted NSW-listed TEC
- Commonwealth and NSW-listed species likely to be at risk of residual adverse direct impacts

An analysis of the extent to which the TEC offset targets are consistent with the BAM credit requirements and meet the principles of the EPBC offsets policy (DSEWPC, 2012) is provided in Part 7.

CONTEXT FOR DEVELOPMENT OF OFFSET TARGETS

Under a strategic biodiversity certification under the BC Act, no guidance is provided about how to determine offset targets for TECs and species and therefore methods were required to be developed for this Assessment Report.

The offset target methods took a risk-based approach and aimed to ensure offsets under the Plan addressed reasonable or actual risks of impacts to each TEC and species and were proportionate to these risks.

This was particularly challenging for species offsets, because the spatial and temporal scale of the Plan means there is an inherent level of uncertainty in the baseline data (both for species habitat and records). The species habitat mapping is very precautionary as it is based primarily on assumed presence (see Part 3) due to land access constraints. The mapping is unlikely to provide an accurate indication of the likelihood of species occurrence within areas impacted by the development (see Box 3) and is not considered to provide a suitable basis alone for determining offsets. This makes it is important to understand the level of risk to each species in determining appropriate offsets rather than take a simplistic view of direct impacts to potential habitat as indicated in the impact statistics.

It is important to note that potential habitat for most species impacted by the Plan will be secured through the offsets required to meet the NSW TEC targets, and for many species, substantial amounts of habitat (hundreds to thousands of hectares) will be secured (see Section 41.6). The Plan's reconciliation accounting process will track the Plan's progress in securing potential habitat for each species in addition to the species offset targets (see Sub-Plan B).

The approach to developing species offset targets took this into account and aimed to provide greater certainty of conservation outcomes for those species likely to be at risk of residual adverse impacts under the Plan. Species offsets for most species are established in terms of 'offset locations' (see definition below) rather than amounts of potential habitat to ensure known habitat and populations will be secured and managed in perpetuity, rather than merely potential habitat with no certainty that the species will benefit from the offset.

BOX 3: HABITAT MAPPING – ACACIA PUBESCENS

The Plan will directly impact 1,377.6 hectares of habitat for *Acacia pubescens* in the Plan Area.

If the offset rules applied, this would require the retirement of 26,395 credits.

This offset amount is not considered to be proportionate to the level of risk from the Plan to this species. The assessment under the EPBC Act for this species, which applied a risk framework to determine the risks of residual adverse impacts to each Commonwealth listed species, concluded this species is at *very low* risk (see Chapter 29).

This was based on several factors, including the following:

- The likelihood of actual impacts occurring was categorised as unlikely. There will be no impacts to known populations, and there is low confidence that the species could occur in the potential habitat to be impacted. The habitat which is to be impacted within GPEC and WSA consists of small, scattered, and isolated patches which are considered unlikely to support the species. Impacted potential habitat within GMAC and Wilton is located outside of the core range of the species, and the species has never been recorded in these localities
- The consequence of any impacts to the species (if they did occur) was categorised as minor. There will be loss of 3.8 per cent of mapped potential habitat in the Plan Area. Species mapping is highly precautionary, with much impacted habitat being mapped beyond the known range of the species, suggesting the species is unlikely to occur in these localities, and as such there is low confidence of species presence in impacted habitat

The expert report for the species (see Supporting Document C) also acknowledges the precautionary nature of the mapping, stating that it is 'precautionarily modelled potential habitat', and does 'not necessarily equate with actual habitat'. The report states that '[i]t is unlikely that a large percentage of the potential habitat identified in the report would actually support [the species] because this species is naturally rare and patchily distributed…'.

THREATENED ECOLOGICAL COMMUNITY OFFSET TARGETS

The Department developed an approach for defining offset targets to ensure that the commitments address the biodiversity values being impacted. The offset target method determined targets based on the:

- Amount (hectares) of each impacted matter
- Conservation status of the impacted matter
- Condition of the impacted matter

This approach is explained in detail in the Conservation Priorities Method that supports the Plan.

Table 8-1 identifies the offset targets for each impacted TEC.

Table 8-1: Offset targets for threatened ecological communities

Matter	Offset target
Commonwealth-listed TECs	
Shale Sandstone Transition Forest	675 ha
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	665 ha
River-Flat Eucalypt Forest on Coastal Floodplains	570 ha
Cooks River Castlereagh Ironbark Forest	125 ha
Coastal Swamp Oak Forest	20 ha
Western Sydney Dry Rainforest and Moist Woodland on Shale	0.2 ha
NSW-listed TECs	
Cumberland Plain Woodland	2,885 ha
Shale Sandstone Transition Forest	1,455 ha

Matter	Offset target
River-flat Eucalypt Forest	505 ha
Shale Gravel Transition Forest	285 ha
Cooks River Castlereagh Ironbark Forest	115 ha
Swamp Oak Floodplain Forest	70 ha
Freshwater Wetlands on Coastal Floodplains	10 ha
Moist Shale Woodland	0.2 ha

SPECIES OFFSET TARGETS

Species offset targets were developed for each Commonwealth and NSW-listed species likely to be at risk of residual adverse impacts from the direct impacts of development under the Plan.

The determination of what species need offsets was based on:

- For Commonwealth-listed species – individual assessments of the level of risk of residual adverse impacts from the direct impacts of development under the Plan on each species, provided in Chapter 29 and 30
- For NSW-listed species – a set of criteria that aims to address the risk of residual adverse direct impacts

The approach to determining risk for Commonwealth and NSW-listed species was different because of the different methods used to assess impacts on these species used in the Assessment Report.

Species offset targets are specified under the Plan in terms of:

- Number of 'offset locations'
- Hectares of potential foraging habitat and important habitat for Swift Parrot
- Hectares of important habitat for Koala

An 'offset location' is a site where one or more populations and habitat of the species has been confirmed through surveys or an expert report as being present. Offset location sites may be reserves or BSA sites. For a biodiversity stewardship site, this means credits representing a reasonable proportion of habitat and/or number of individuals of a local population of the threatened species are purchased and retired against the Plan's offset targets.

Specifying offset targets in terms of 'offset locations' rather than amounts of potential habitat was considered the most robust approach. This is because it ensures known habitat and populations will be secured and managed in perpetuity, rather than merely potential habitat with no certainty that the species will benefit from the offset.

For Swift Parrot, both potential foraging habitat and important habitat were used as the offset targets. This species is a species credit species for important habitat under the BAM. Both potential foraging habitat and important habitat has been mapped in the Plan Area and will be impacted by the development.

For Koala, important habitat (defined as primary, secondary and tertiary corridors – see Part 3) was used as the offset target as this has been mapped in the Plan Area and will be impacted by the development.

Species offset targets for Commonwealth and NSW-listed species are identified in Table 8-2.

Table 8-2: Offset targets for species

Species	Cth status	NSW status	Offset target
Cynanchum elegans	E	E	2 offset locations
Dillwynia tenuifolia	-	V	3 offset locations
Grevillea juniperina subsp. *juniperina*	-	V	3 offset locations
Haliaeetus leucogaster	-	V	1 offset location
Hibbertia fumana	-	CE	1 offset location

Species	Cth status	NSW status	Offset target
Hibbertia puberula	-	E	1 offset location
Hieraaetus morphnoides	-	V	1 offset location
Koala (*Phascolarctos cinereus*)	V	V	570 ha of important habitat
Lophoictinia isura	-	V	1 offset location
Marsdenia viridiflora subsp. *viridiflora*	-	E	2 offset locations
Cumberland Plain Land Snail (*Meridolum corneovirens*)	-	E	3 offset locations
Persoonia nutans	E	E	2 offset locations
Pimelea spicata	E	E	3 offset locations
Pultenaea parviflora	V	E	2 offset locations
Pultenaea pedunculata	-	E	2 offset locations
Southern Myotis (*Myotis macropus*)	-	V	1 offset location
Swift Parrot (*Lathamus discolour*)	CE	E	4,410 ha of potential foraging habitat, including 100 ha of important habitat

Commonwealth-listed species

The determination of which Commonwealth-listed species need offsets was based on assessments of the level of risk of residual adverse direct impacts undertaken for each species in Chapter 29 and 30. A detailed description of the risk framework applied to assess each Commonwealth-listed species is provided in Chapter 29 and 30.

Risk is generally considered to be the combination of the likelihood and consequence of an event occurring. In summary, the risk framework involved consideration of:

- Likelihood that a species will be directly impacted due to impacts to populations and/or potential habitat, taking into account records and potential habitat mapping, as well as level of confidence in these
- Consequence of the direct impacts, taking into account conservation status, SAII entities, endemicity, and thresholds that were specified for the amount of direct impact on populations and potential habitat due to the development

The risk framework also included an assessment of the likelihood and consequence of impacts due to fragmentation, as well as an amended approach to determining risk for wide-ranging fauna (such as Swift Parrot).

The species considered to require offsets were those with a high or medium risk of residual adverse impacts. These were:

- *Cynanchum elegans*
- Koala
- *Persoonia nutans*
- *Pimelea spicata*
- *Pultenaea parviflora*
- Swift Parrot

Offsets were not considered necessary for species considered to be at low or very low risk.

The method to determine the 'offset location' targets for each species was based on a combination of the identified level of risk of residual adverse direct impacts (high or medium) and conservation status. Consistent with the approach for determining offset targets for TECs, Swift Parrot, and Koala, species with a higher conservation status (as well as a higher risk of residual adverse direct impacts) required larger offset targets. This is shown in Table 8-3.

Table 8-3: Method to determine offset locations for Commonwealth-listed species needing offsets

Risk of residual adverse direct impacts	Conservation status		
	V	E	CE
High	2 offset locations	3 offset locations	4 offset locations
Medium	1 offset locations	2 offset locations	3 offset locations

Offset targets for Swift Parrot and Koala were determined by applying an approach developed by the Department consistent with the approach for determining TEC targets. As for TECs, targets were determined based on the amount (hectares) of habitat of each matter impacted by the development, and were driven by two key principles:

- Impacts to higher conservation status matters require more offsets that lower status matters
- Impacts to higher condition habitat require more offsets than lower condition habitat

This approach is explained in detail in the Conservation Priorities Method that supports the Plan.

NSW-listed species

NSW-listed candidate species credit species needing offset targets were determined based on a set of criteria that aimed to reflect the level of risk of residual adverse impacts to the species. Consistent with the BAM, ecosystem credit species are addressed through offset targets for NSW TECs/PCTs and were not considered for specific species targets.

The criteria used to determine the NSW-listed species needing offset targets were direct impacts to:

- > 5 per cent of records in the nominated areas, or
- > 5 per cent of potential habitat in the nominated areas, or
- > 1 per cent of potential habitat in the nominated areas for SAII entities or endemic/largely endemic species

It is important to note that where a NSW-listed species was assessed under the Commonwealth approach as it was also a Commonwealth-listed species, the determination of whether the species needed an offset target and the offset target needed was based on the approach taken for the Commonwealth-listed species (therefore this criteria was only applied to NSW-only listed species, and not to NSW-listed species that were also Commonwealth-listed).

The method to determine the 'offset location' targets for each NSW-only listed species was based on a combination of the identified level of risk of residual adverse direct impacts (in terms of per cent impacts to records or potential habitat, with lower thresholds for SAII entities and endemic/largely endemic species) and conservation status.

The method is shown in Table 8-4, and Table 8-5 for SAII entities and endemic/largely endemic species.

Table 8-4: Method to determine offset locations for NSW-only listed species needing offsets

Impacts to potential habitat or records as % of total within nominated areas	NSW listing status		
	V	**E**	**CE**
Substantial (> 20%)	1 offset location	2 offset locations	3 offset locations
Small (5–20%)	0 offset location	1 offset location	2 offset locations

Table 8-5: Method to determine offset locations for NSW-only listed species that are SAII entities or endemic

SAII, or Endemic, largely endemic*	Impacts to potential habitat		
	Minimal (1-5%)	**Small (5-10%)**	**Substantial (>10%)**
Yes	1 offset location	2 offset locations	3 offset locations

*A species was considered largely endemic if greater than 90 per cent of total records in NSW occur in the Cumberland IBRA subregion

To determine an appropriate set of criteria for NSW-only listed species, a range of alternative impact thresholds and offset location scenarios were tested and analysed. It should be noted that like all threshold approaches the numbers are arbitrary to a degree. However, the thresholds are considered to be appropriate because they:

- Reflect the nature of the baseline data. In particular the potential habitat mapping which has been generated across the nominated areas is precautionary in many cases and over-maps habitat
- Are structured around conservation status
- Reflect the knowledge of the assessment team about the level of risk to species

It is acknowledged that the criteria may exclude NSW-only listed species (that are not SAII entities or endemic species) that are subject to impacts to records of up to but less than 5 per cent of the total within the nominated areas, or up to but less than 20 per cent if the species is vulnerable. Of the excluded species with records impacted, all species are wide-ranging and highly mobile fauna (two cockatoo species and one owl species). Impacts on records for wide-ranging species are much less of a reliable indicator of risk of impacts relative to restricted species as records are less indicative of the importance of a location to the species. This threshold is therefore considered appropriate in this context.

Note that *Tyto novaehollandiae* is eligible under the criteria for 1 offset location due to impacts to records. However, this species was not included as an NSW-listed species requiring an offset given only 1 record of the species is being impacted (of a total of 2). Furthermore, the species is wide-ranging and highly mobile (impacts on records are much less of a reliable indicator of risk of impacts) and only 0.11 per cent of total habitat in the nominated areas will be impacted.

Table 8-6 identifies the NSW-only listed species needing offset targets and the criteria that triggered the need for a target. Note that for several species, the per cent impacts to records seem large, however very few records are being impacted (for example,

Table 8-6: NSW only-listed species (not Commonwealth-listed) that need offset targets

Species	Status	Criteria triggering the need for a species offset
Dillwynia tenuifolia	V	Direct impacts to 22.5 per cent of potential habitat (endemic species) within the nominated areas
Grevillea juniperina subsp. *juniperina*	V	Direct impacts to 18.7 per cent of potential habitat (endemic species) within the nominated areas
Haliaeetus leucogaster	V	Direct impacts to 34.6 per cent of records within the nominated areas
Hibbertia fumana	CE	Direct impacts to 4.3 per cent of potential habitat (endemic and SAII species) within the nominated areas
Hibbertia puberula	E	Direct impacts to 4.5 per cent of potential habitat (endemic species) within the nominated areas
Hieraaetus morphnoides	V	Direct impacts to 26.1 per cent of records, and 1.6 per cent of potential habitat (SAII species) within the nominated areas
Lophoictinia isura	V	Direct impacts to 2 per cent of potential habitat (SAII species) within the nominated areas
Marsdenia viridiflora subsp. *viridiflora*	E	Direct impacts to 9.6 per cent of potential habitat (SAII species) within the nominated areas
Meridolum corneovirens	E	Direct impacts to 10.7 per cent of potential habitat (endemic species) within the nominated areas
Pultenaea pedunculata	E	Direct impacts to 33.3 per cent of records and 10.6 per cent of potential habitat within the nominated areas
Southern Myotis	V	Direct impacts to 20.6 per cent of potential habitat (endemic species) within the nominated areas

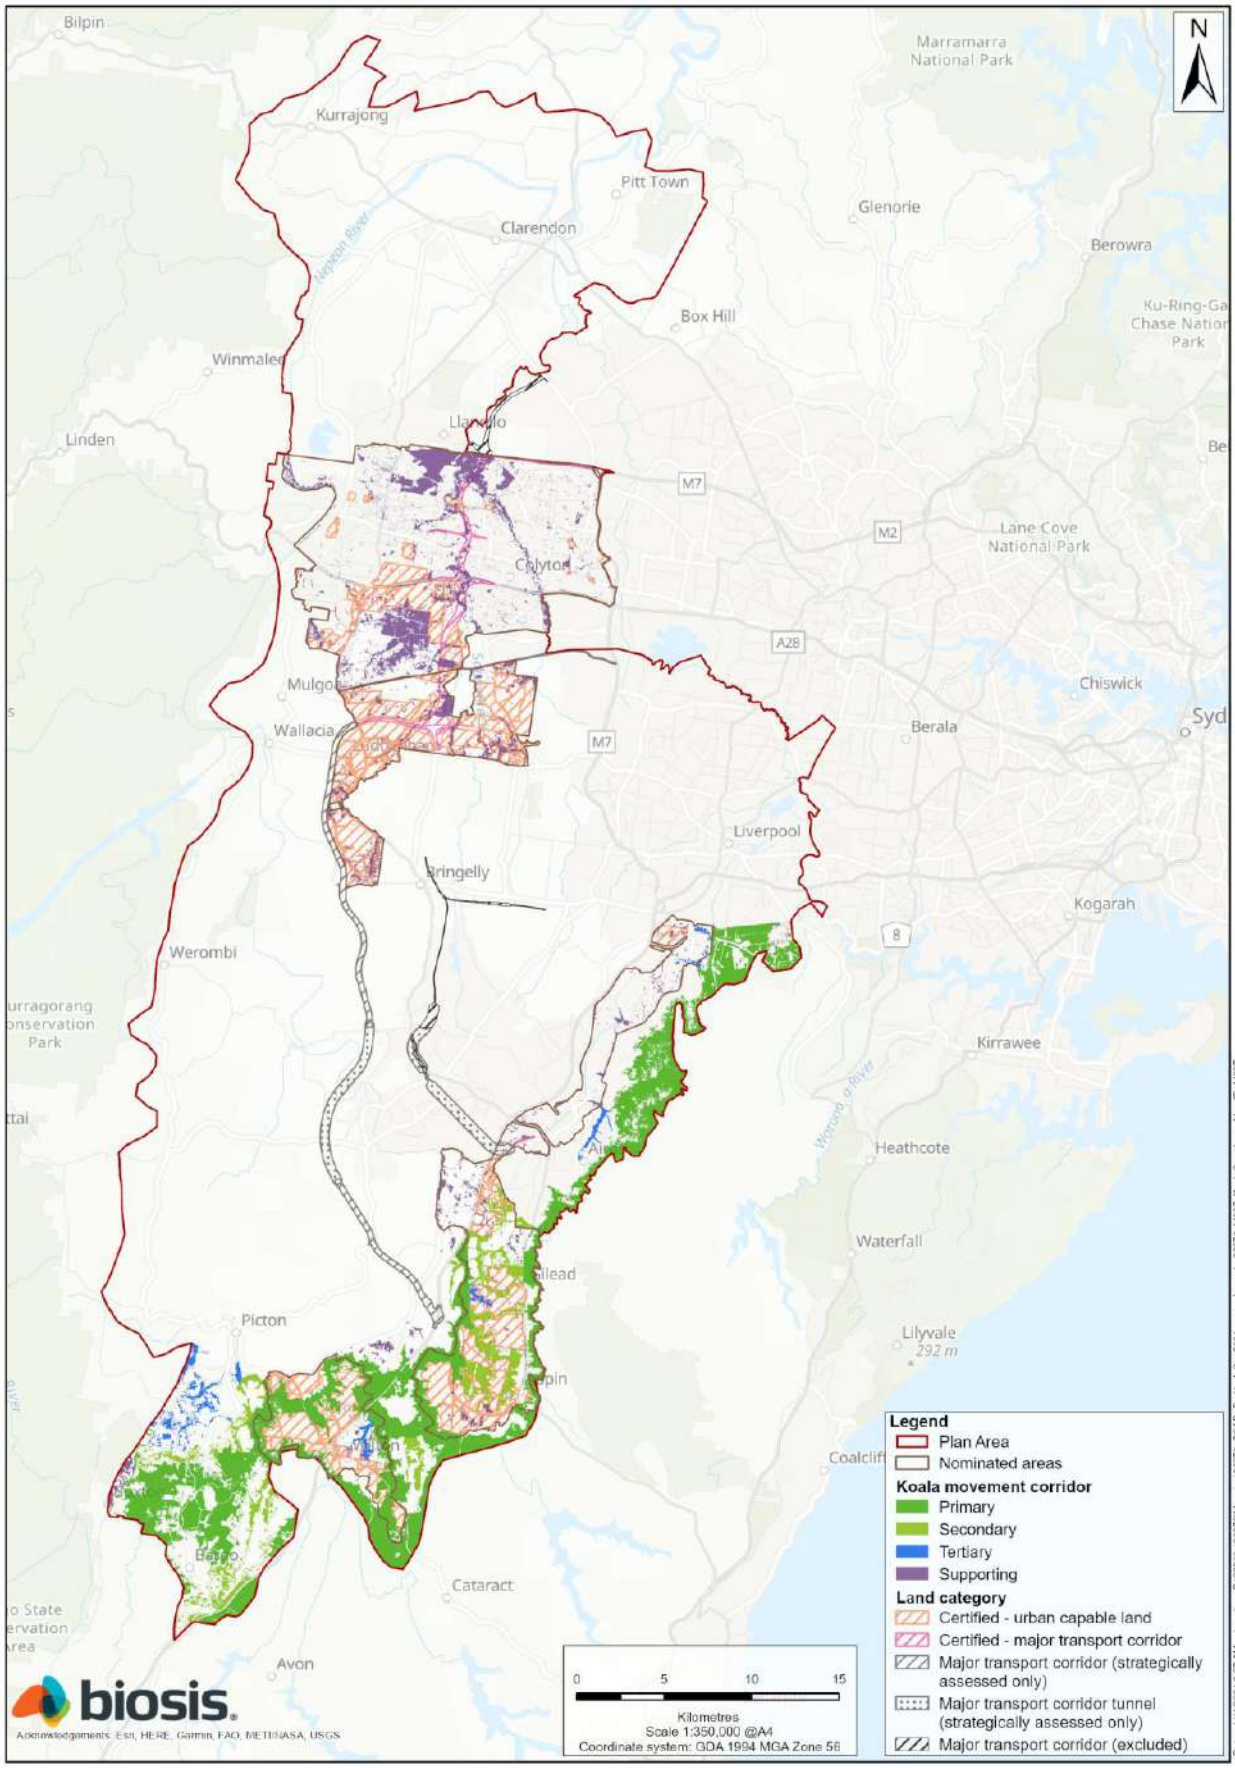

Figure 8-2: Key Koala movement corridors within the Plan Area

9 Implementation of the Plan

9.1 INTRODUCTION

The Plan includes a range of commitments and actions and implementation mechanisms to support its delivery.

This Chapter describes how the Plan will be implemented, including:

- Implementation mechanisms
- Roles and responsibilities
- Funding
- Monitoring, evaluation and reporting and adaptive management
- Compliance

9.2 IMPLEMENTATION MECHANISMS

The Department has committed to undertake the development under the Plan in accordance with the Plan and any conditions of approval (Commitment 1). This commitment will be delivered through several actions, including:

- Integrating the Plan into the planning delivery framework for the nominated areas (see below)
- Monitoring implementation through the Plan's evaluation program (see Section 9.5)
- Requiring proponents of essential infrastructure to notify the Department of any development in avoided land, including how the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development have been addressed
- Implementing the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development, including Appendix A of the Plan, by:
    - Notifying proponents of essential infrastructure of their obligations under the EPBC Act, including when development does not have Part 10 EPBC Act approval under the Plan
    - Monitoring the impacts of development on avoided land
    - Monitoring compliance with the avoidance, mitigation and offset commitments under the Plan
    - Providing annual updates to DAWE
    - Sharing information and data to assist councils and infrastructure providers with implementation
    - Undertaking monitoring and auditing of infrastructure construction and operation as required, to ensure adequate mitigation measures are being applied
- Undertaking a formal modification to the Plan's strategic biodiversity certification if required, to adjust the boundaries of the certified-urban capable land in circumstances where:
    - Minor adjustments are identified at the site level
    - Updates are consistent with the Avoidance Criteria and supported by a BAM accredited assessor
    - Residual impacts to biodiversity, including MNES, are mitigated and offset in accordance with the Biodiversity Assessment Method (or equivalent) and EPBC Act Environmental Offsets Policy, 2012 for any EPBC Act matters not covered by the BAM
- Undertaking a formal modification to the Plan's strategic biodiversity certification to seek NSW biodiversity approvals on behalf of Deerubbin Local Aboriginal Land Council

9.2.1 NSW PLANNING SYSTEM

To support a strategic-led planning framework in NSW, the Plan informs the strategic and precinct planning processes that apply to the nominated areas for relevant local government areas in Western Sydney.

Implementation of the Plan will be supported by a range of planning mechanisms under the EP&A Act. These mechanisms support the delivery of both the development and conservation program under the Plan.

PLANNING DELIVERY FRAMEWORK

The planning delivery framework for the nominated areas includes a series of strategic land-use plans, including:

- Structure plans – these are high-level plans that set out the broad land-use intentions for an area and provide the broad framework for more detailed planning of a specific area or precinct
- Precinct plans – these are made under a place-based SEPP, such as the Growth Centres SEPP and Western Sydney Aerotropolis SEPP, and function in the same way as a Local Environmental Plan (LEP). Precinct plans identify permitted land uses and the location and phasing of infrastructure. Precinct plans apply zoning as well as development controls to guide the planning and design of developments permitted by the land use zone. Precinct plans are required to be consistent with the structure plans
- Neighbourhood plans – these show the detailed design and layout of a future neighbourhood and are required to be consistent with precinct plans

Structure plans will be prepared by the relevant planning authority for each nominated area and will show broad land use zones and the boundaries of the urban capable land and will identify the avoided land as land that is not suitable for urban development, consistent with the Plan. Structure plans guide development within each nominated area. They set the vision and strategic direction of each area consistent with the Greater Sydney Region Plan and district plans, and they provide a line of sight from these plans through to planning at a precinct scale.

Land use zoning for nominated areas will be consistent with the boundaries of urban capable land. In some nominated areas, precinct plans guide structure plans that lay out the strategic intent of a precinct. This occurs under the Growth Centres SEPP. In other nominated areas such as a part of the Western Sydney Aerotropolis, the place-based Western Sydney Aerotropolis SEPP determines the zoning for precincts.

Rezoning under each precinct plan will be implemented through the relevant Environmental Planning Instrument (EPI), such as the Growth Centres SEPP, the Aerotropolis SEPP or the relevant local LEP.

Neighbourhood plans will be used to implement more detail rezoning (e.g. allocating specific types of residential zones within a precinct). Where this occurs, a neighbourhood plan would result in rezoning via the LEP.

NEW PLANNING MECHANISMS TO SUPPORT PLAN IMPLEMENTATION

The Department will introduce several planning mechanisms or amendments to the planning system to support the planning delivery framework and implementation of the Plan. These are:

- SEPP (Strategic Conservation Planning), made under the EP&A Act
- Ministerial Direction made under the EP&A Act
- Development Control Plan (DCP) template
- Cumberland Plain Conservation Plan Guideline for Infrastructure Development made under the EP&A Regulation 2000
- Amendment to the EP&A Regulation 2000

These planning mechanisms are summarised in Table 9-1.

The key planning mechanism to support implementation of the Plan is a new EPI made under the EP&A Act – the SEPP (Strategic Conservation Planning). The objectives of the proposed SEPP are to:

- Ensure that development in the nominated areas is consistent with biodiversity certification under the BC Act and the strategic assessment under the EPBC Act
- Facilitate appropriate development on urban capable land in the nominated areas
- Identify and protect areas of high biodiversity value (these are the avoided lands) or regionally significant biodiversity value (this is the SCA land)
- Avoid and minimise impacts from future development in areas of high biodiversity value (avoided lands and SCA)
- Support the acquisition of priority areas with high biodiversity value as conservation lands (these are the lands to be secured for conservation within the SCA under the conservation program)

Table 9-1: Key planning mechanisms or processes to support implementation of the Plan

Planning mechanism	Description	How it supports implementation of the Plan	Land it applies to
SEPP (Strategic Conservation Planning)	A SEPP is an environmental planning instrument (EPI). EPIs are legally binding strategic plans made under Part 3 of the EP&A Act, and include SEPPs and LEPs SEPPs are made by the Minister and can specify planning controls for matters of State or Regional significance. Planning controls specify requirements for specific areas and/or for certain types of development and identify approval and assessment pathways for different development types	The SEPP (Strategic Conservation Planning) provides for the following: • Identifies the location of urban capable land, avoided land, the SCA and conservation lands identified for acquisition on maps • Applies development controls to avoided land and the SCA to limit the impact of future development and subdivisions under Part 4 of the EP&A Act and ensure biodiversity values are protected if development is proposed on these lands • Requires asset protection zones (APZ) for development on urban capable land to be located within urban capable land (and not within avoided land) • Requires infrastructure under Part 4 of the EP&A Act on avoided land to comply with the *Cumberland Plain Conservation Plan Guidelines for Infrastructure Development* • Identifies the authority with the power to acquire conservation lands within the SCA to be secured as offsets under the conservation program (if the land is needed to be acquired under the *Land Acquisition (Just Terms Compensation) Act 1991*) ***Development controls for avoided land and the SCA*** The development controls identify key biodiversity values that are the focus of the Plan, such as TECs, threatened species and their habitats, koala habitat and corridors, and MNES, and requires the consent authority to ensure any future development avoids and minimises impacts on these values. The controls: • Require development consent to clear native vegetation • Require development to avoid and minimise native vegetation and compensate through revegetation on the land for impacts that cannot be avoided • Require the consent authority in granting consent to consider impacts to specific biodiversity values, including TECs and species and habitat connectivity • Limit when the consent authority can grant consent. For example, the consent authority must be satisfied that the development avoids any adverse impacts to the specific biodiversity values described in the SEPP • Limit when the consent authority can grant consent for subdivisions The development controls are similar between avoided land and the SCA, with several	Avoided land SCA Urban capable land

Planning mechanism	Description	How it supports implementation of the Plan	Land it applies to
		differences to account for the different purposes of these lands in relation to the Plan Note: • Existing land use zones and development permissibility in avoided land and SCA are not affected by the proposed SEPP • Development on avoided land and SCA does not have approval under the Plan (except for 'essential infrastructure' under EPBC Act where it meets the requirements of the Plan) and will need to address any relevant requirements of the BC Act/EPBC Act • The SEPP (Strategic Conservation Planning) clarifies that the SEPP (Koala Habitat Protection) 2020 does not apply to urban capable land	
Ministerial Direction	Ministerial Directions are legally binding instructions issued by the Planning Minister under section 9.1 of EP&A Act to bodies with functions under the Act, including to councils for planning proposals and the preparation of LEPs	The Department will introduce a Ministerial Direction under section 9.1 of the EP&A Act that applies to planning proposals by planning proposal authorities (usually councils) in avoided land and the SCA. The Direction: • Requires the planning proposal to protect or enhance and/or minimise impacts to native vegetation, riparian corridors, TECs and species, Koala habitat and corridors, and habitat connectivity and several other biodiversity values • Prevents planning authorities from rezoning land inconsistent with the objectives of avoided land or the SCA	Avoided land SCA
DCPs and DCP template	DCPs provide detailed planning and design guidelines, including development controls. DCPs are made under Division 3.6 of the EP&A Act. Any development assessed under Part 4 of the EP&A Act must consider the relevant DCP. DCPs are considered by consent authorities in determining development applications	DCPs will be prepared for each nominated area. Some DCPs will led by the Department, while some DCPs will be led by councils DCPs will include the mitigation measures identified in the Plan to address indirect and prescribed impacts on biodiversity values and will require planning authorities to consider these in granting consent to development under Part 4 of the EP&A Act The Department has prepared a DCP template that provides model provisions to help ensure the mitigation measures identified in the Plan are incorporated into DCPs and applied consistently across the nominated areas The Department will: • Incorporate development controls in the DCP template into Department led DCPs • Work with local councils to incorporate the development controls in the DCP template into council led DCPs • Audit DCPs to ensure the development controls are incorporated	Urban capable land

Planning mechanism	Description	How it supports implementation of the Plan	Land it applies to
Cumberland Plain Conservation Plan Guideline for Infrastructure Development	Clause 228 of the EP&A Regulation 2000 allows the Planning Secretary to establish guidelines in relation to any activity for the factors a determining authority must take into account when considering the likely impact on the environment under Part 5 of the EP&A Act	The Department will prepare a guideline under clause 228 of the EP&A Regulation – the Cumberland Plain Conservation Plan Guideline for Infrastructure Development – that applies to infrastructure development, including: • Activities under Part 5 of the EP&A Act • 'Essential infrastructure' under Part 4 of the EP&A Act, as defined in the Plan The guideline ensures infrastructure development within avoided land, the SCA and urban capable land avoids and minimises impacts to biodiversity values and mitigates indirect impacts in accordance with the requirements of the Plan ***Development controls for avoided land, the SCA and urban capable land*** The guideline includes development controls for: • 'Essential infrastructure' (as defined in the Plan) on avoided land to ensure consistency with the Plan's EPBC Act approval. This must: o Avoid and minimise impacts to biodiversity values and specific TECs and species, including koala habitat and corridors (these matters were identified at risk from essential infrastructure in this Assessment Report) o Identify and implement mitigation measures to address indirect and prescribed impacts on biodiversity values, including installing and maintaining the integrity of koala exclusion fencing o Offset any impacts in accordance with the BC Act and BAM • Infrastructure activities under Part 5 of EP&A on avoided land and SCA. This must: o Avoid and minimise impacts to biodiversity values, including TECs and species and koala habitat and corridors o Install and maintain the integrity of koala exclusion fencing o For the SCA, consider the impact on biodiversity values, habitat connectivity and the potential for ecological restoration of the land • Infrastructure activities under Part 5 of EP&A Act on urban capable land. This must implement specific set of mitigation measures to address indirect and prescribed impacts (these measures were identified in this Assessment Report as needed to address the impacts of infrastructure and are included in Appendix E of the Plan) The guideline is supported by the SEPP and EP&A Regulation amendment, which includes notification and reporting requirements for infrastructure on avoided land. The guideline specifies what public authorities must include in the notification, including a plan of works,	Avoided land SCA Urban capable land

Planning mechanism	Description	How it supports implementation of the Plan	Land it applies to
		an ecology report that assesses impacts on biodiversity values, how the requirements of the guideline have been addressed, and proposed mitigation measures Note: • Development on avoided land and SCA does not have approval under the Plan (except for 'essential infrastructure' under EPBC Act where it meets the requirements of the Plan) and will need to address any relevant requirements of the BC Act/EPBC Act	
Amendment to EP&A Regulation 2000	The EP&A Regulation is made under the EP&A Act and provides details about how the Act is administered	The amendment introduces requirements into the EP&A Regulation 2000 for public authorities to notify the Department about activities under Part 5 of the EP&A Act proposed on avoided land. Public authorities must: • Notify the Department of the proposed activity • Include a statement of consistency of the proposed activity with the *Cumberland Plain Conservation Plan Guidelines for Infrastructure Development* • Consider any response from the Department about the activity	Avoided land

9.2.2 IMPLEMENTATION STRATEGIES AND PROCESSES

The Plan includes several actions that provide for the preparation of detailed implementation documents that will support the implementation of the Plan. Key implementation documents include (see Chapter 8):

- Conservation Land Implementation Strategy to guide the securing of conservation land
- Restoration Implementation Strategy
- Weed control and pest animal strategies to guide delivery of the weed and pest programs
- Fire Management Strategy to guide fire management
- Reconciliation accounting process to track progress in meeting offset targets
- Written agreements with delivery partners to set out delivery arrangements
- Compliance Strategy

9.3 ROLES AND RESPONSIBILITIES

The governance framework for the Plan is shown in Figure 9-1.

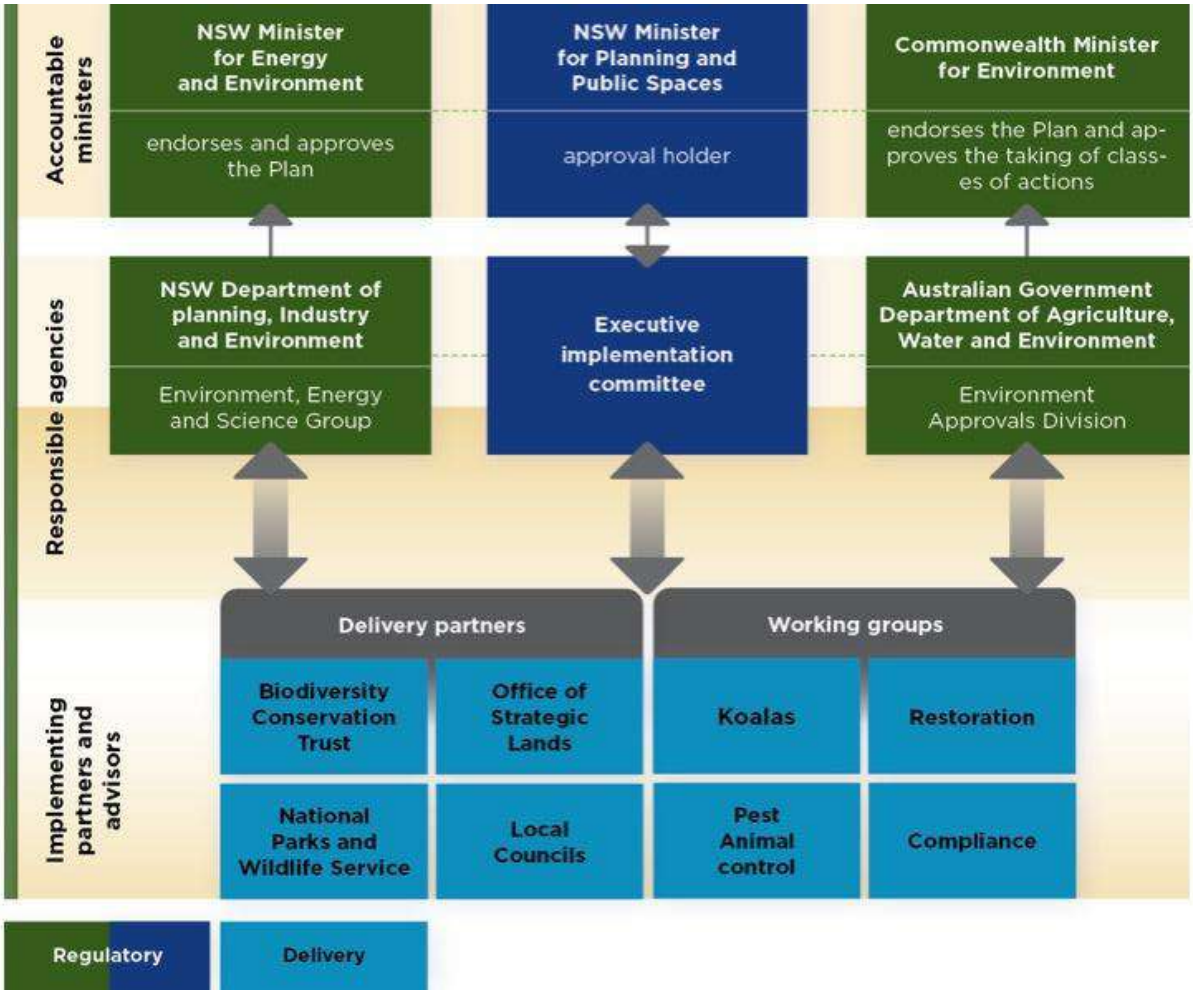

Figure 9-1: Governance framework for the Plan

9.3.1 RESPONSIBLE AGENCIES

The Department is the responsible agency for implementing the Plan and meeting regulatory requirements. The major transport corridors will be administered by Transport for NSW.

The Department's roles will include:

- Central coordination and management of implementation, including:

  - Reporting on the evaluation program
  - Contract and grant management
  - Reports for publication
  - Management of potential compliance breaches
- Working with delivery partners and technical working groups to ensure efficient and effective implementation
- Periodically reporting to approval bodies and relevant NSW and Commonwealth ministers

An executive implementation committee has been established that includes executive level representatives from the Department, approval bodies and partner agencies to act as a steering committee for the Plan. The executive committee will be a key decision-making authority for implementing the Plan.

9.3.2 DELIVERY PARTNERS AND ADVISORS

A range of delivery partners will be responsible for delivering programs under the Plan, including:

- NSW Government bodies, such as:
  - Office of Strategic Lands – key responsibilities include acquisition of reserves for the reserve program
  - National Parks and Wildlife Service – key responsibilities include long-term management of reserves established under the *National Parks and Wildlife Act 1974*
  - Biodiversity Conservation Trust – key responsibilities include delivering the BSA program
- Councils –will play a role in delivering the conservation program and ensuring conservation is embedded in local planning controls. This includes following section 9.1 Directions in considering Planning Proposals
- Community organisations – key responsibilities could include management of smaller community reserves
- Private landholders – may enter into BSAs for conservation on their land

Service level agreements or memorandums of understanding are being prepared as part of the process of engaging delivery partners to clarify the roles and responsibilities of each delivery partner and to ensure accountability.

9.4 FUNDING

The Department will be responsible for funding the Plan's implementation to 2056.

To date, the NSW Government has committed $114 million in the first five years to implement the Plan, including a set of priority conservation actions (see section 8.2.1 above). The Department will be responsible for funding the Plan's implementation to 2056.

The Department will establish arrangements to recover costs of the conservation program from developers (a development levy) within the nominated areas through the Special Infrastructure Contributions (SICs) program or other contribution type. This will include:

- Establishing a Trust or other financial arrangement to administer receipts and expenditure to implement the Plan
- Establishing arrangements to determine how funding decisions will be made, administered, and reported

Transport for NSW is responsible for funding a proportion of the conservation program consistent with their offset obligations associated with the impacts of the major transport corridors on biodiversity values. Transport for NSW will provide funding to the Department in advance of impacts. Finding arrangements will be in accordance with an agreement to be established between Transport for NSW and the Department.

9.5 MONITORING, EVALUATION, REPORTING AND ADAPTIVE MANAGEMENT

The Plan commits to implementing an evaluation program for the Plan within the first year of implementation, which sets out requirements for monitoring, evaluation, reporting and adaptive management (Commitment 25).

The evaluation program will help to assess the progress of the Plan and support its implementation and will be guided by an evaluation plan that is being developed to meet NSW Government guidelines for program evaluation.

The evaluation program will be supported by a monitoring program and evaluation database that will collect and store information across the Plan's key environmental, social, and economic indicators.

The key elements of the evaluation program are outlined in Figure 9-2 and details are provided in Sub-Plan A.

The evaluation program provides for:

- Monitoring of the delivery of actions and commitments and achievement of outcomes
- Evaluation of the Plan to inform adaptive management responses
- Public reporting on progress in delivering the Plan

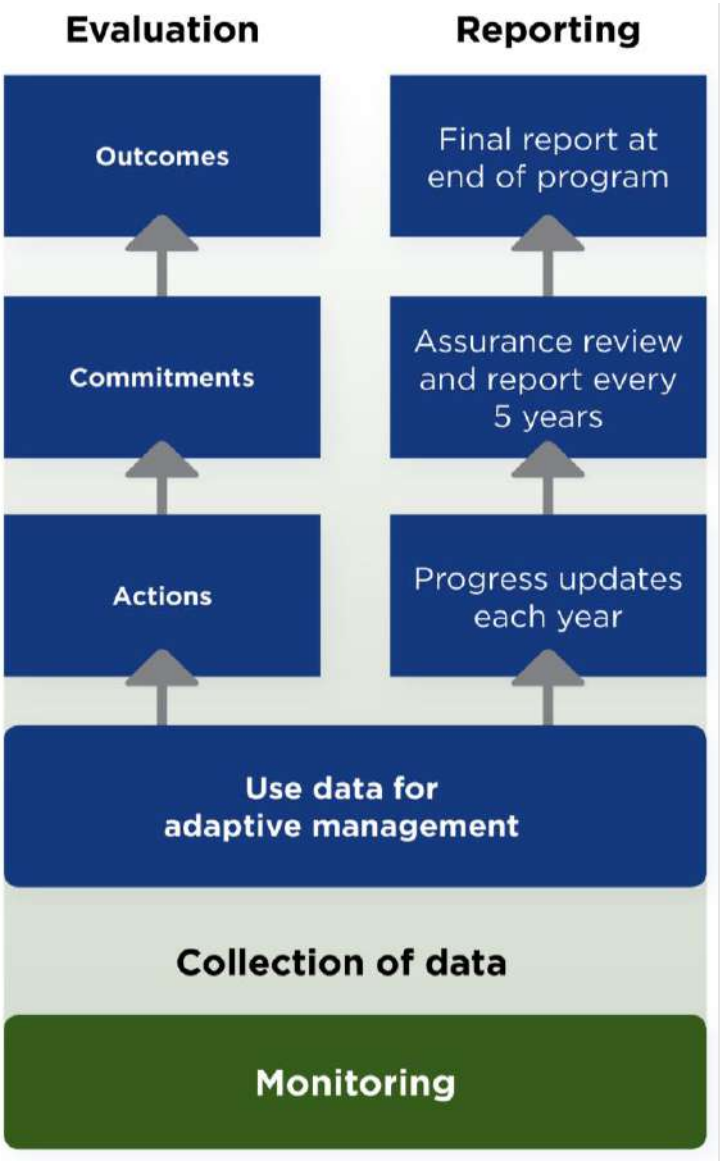

Figure 9-2: Key elements of the evaluation program (MERI framework)

MONITORING

The evaluation program will collect, assess, and store data to evaluate and report on the progress of the Plan. Monitoring for the evaluation program will ensure that data relating to the Plan's outcomes is collected and used to inform the evaluation program.

The Plan will establish a monitoring and data collection methodology and establish formal agreements with delivery partners that include requirements relating to data collection, management and sharing arrangements.

The Department will collect baseline data on biodiversity values through various methods, including vegetation plots, species surveys and rapid assessments. The baseline data will be compared with data collected on specific biodiversity values at specific locations throughout the implementation of the evaluation program to evaluate the effectiveness of the Plan over time and to ensure the Plan is delivering its commitments, actions, and outcomes.

EVALUATION

The effectiveness of the Plan's actions in achieving the environmental, social, and economic outcomes will be evaluated on an ongoing basis to meet reporting requirements and to ensure transparency and accountability.

Evaluations will be undertaken regularly throughout the implementation of the Plan and will aim to:

- Determine the effectiveness of actions, targets, and commitments to deliver outcomes
- Reconsider assumptions made as part of the program logic
- Determine the influence of external factors outside the control of the Plan
- Inform any necessary adaptive management decisions to the implementation of the Plan

The Department will develop and implement the evaluation program within the first year of the Plan's implementation.

PUBLIC REPORTING

The Department will prepare an annual progress update on the delivery of the Plan's commitments and actions, including reporting on program revenue and expenditure.

The Department will also collate finer scale program and project reporting from the relevant delivery partners more frequently, which will be provided to the executive implementation committee to support evaluations.

The NSW Government will commission a comprehensive, independent review on the status of implementation of the Plan and its outcomes every five years over the life of the Plan. The results of the independent review will be submitted in a report to the NSW Minister for Planning and Public Spaces and provided to the NSW Minister for the Environment and the Commonwealth Minister for the Environment.

The Department will undertake internal process reviews of the Plan's implementation at the mid-term point (2.5 years) between independent reviews and provide these to key delivery partners and stakeholders.

The annual updates, mid-term reviews and five-yearly independent reviews will be made publicly available on the Department's website.

ADAPTIVE MANAGEMENT

The Plan will be implemented adaptively to ensure the commitments and actions are delivered and the outcomes are achieved efficiently and effectively. Adaptive management will be triggered on the basis of the findings of the evaluations and will be informed by the monitoring data collected as part of the evaluation program.

The approach to adaptive management under the Plan is described in Chapter 16.

9.6 COMPLIANCE

The Plan includes a commitment to implement a compliance program to ensure compliance with the Plan and conditions of approval (Commitment 26).

A compliance strategy will be prepared under the Plan to ensure that the development occurs in accordance with the Plan and conditions of approval. The compliance strategy will:

- Identify relevant compliance mechanisms
- Set out compliance monitoring and auditing priorities and processes
- Set out procedures and protocols for taking compliance action
- Identify roles and responsibilities for compliance monitoring and action

A compliance and implementation working group will be established comprising the Department, councils, and other relevant stakeholders to guide compliance activities under the Plan and the development of the compliance strategy.

Reporting on compliance will be an important part of the evaluation program. Compliance reporting will be included in all aspects of reporting under the evaluation program, including regular reporting to the executive implementation committee, annual progress updates, mid-term review and the independent five-yearly review.

The Department will prepare reports at least every two years on any identified breaches with commitments and approval conditions, such as through auditing of development consent conditions.

Where non-compliance is identified, the Department will take the following broad steps:

- The regulator will review the deviation or non-compliance and consider its importance
- The regulator advises that either:
    - The deviation or non-compliance is minor or trivial or did not occur and no further action is required
    - The deviation or non-compliance requires corrective action
- If corrective action is required, relevant parties will be provided with an opportunity to correct the non-compliance

CUMBERLAND PLAIN ASSESSMENT REPORT

PART 2 ATTACHMENT

ATTACHMENT A – COMMITMENTS AND ACTIONS

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

DOCUMENT TRACKING

PREPARED BY:	
DATA:	N/A
CONTENT:	Taken from *Sub-Plan A: Conservation Program and Implementation (2021),* produced by the Department of Planning, Industry and Environment
REVIEWED BY:	
OPEN LINES:	Peter Hemphill (Open Lines)
ACCREDITED ASSESSOR:	N/A
VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 2 Attachment Contents

A. Commitments and actions

These commitments and actions have been taken directly from *Sub-Plan A: Conservation Program and Implementation (2021)* produced by the Department of Planning Industry and Environment. The following tables outline the commitments, their relevant actions and the timing of implementation of the commitments and actions under the Plan.

DEVELOPMENT ACTIONS

Table A-1: Development actions under Sub-Plan A

Commitments	Actions	Timing
Commitment 1 Development will be undertaken in accordance with the Plan and any conditions of approval. This applies to the following classes of actions: • urban and industrial • infrastructure • intensive plant agriculture • major transport corridors	1. Integrate the Plan into the planning delivery framework for the nominated areas through mechanisms including an environmental planning instrument with, development controls, a Ministerial Direction under section 9.1 of the *Environmental Planning and Assessment Act 1979*, and Cumberland Plain Conservation Plan Guidelines for Infrastructure Development (Commitments 2, 4, 6, 7, 13, 14). 2. Monitor the implementation of urban and industrial development, infrastructure, major transport and intensive plant agriculture through the Plan's evaluation program to ensure development is consistent with the Plan. This includes the Plan's: a. Commitments for avoiding, minimising, mitigating and offsetting impacts b. Reporting and compliance requirements c. Class of action approvals (EPBC Act); strategic biodiversity certification order (BC Act) 3. Require proponents of essential infrastructure to notify the department of any development or activity in avoided land, including how the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development have been addressed. 4. Implement the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development, including Appendix A of the Plan by: a. Notifying proponents of essential infrastructure of their obligations under the EPBC Act, including when development does not have Part 10 EPBC Act approval under the Plan b. Monitoring the impacts of development on the avoided land c. Monitoring compliance with the avoidance, mitigation and offset commitments under the Plan, relevant to these Guidelines d. Providing annual updates to Australian Government Department of Agriculture Water and Environment e. Share information and data as required to assist councils and infrastructure providers to	Action 1: Before start of Plan Actions 2,3,4: Life of Plan Action 5: Years 1-10 Action 6: Year 1

Commitments	Actions	Timing
	implement these Guidelines f. Undertaking monitoring and audit of infrastructure construction and operation as required, to ensure adequate mitigation measures are being applied 5. Undertake a formal modification to the Plan's strategic biodiversity certification if required, to adjust the boundaries of the certified-urban capable land in circumstances where: a. Minor adjustments are identified at the site level b. Updates are consistent with the avoidance criteria and supported by a BAM accredited assessor c. Residual impacts to biodiversity, including MNES, are mitigated and offset in accordance with the Biodiversity Assessment Method (or equivalent) and EPBC Act Environmental Offsets Policy, 2012 for any EPBC Act matters not covered by the BAM 6. Progress and submit (subject to compliance with legislative requirements) a modification of the strategic biodiversity certification under the Biodiversity Conservation Act 2016 to include lands proposed by Deerubbin Local Aboriginal Land Council	

CONSERVATION PROGRAM

COMMITMENTS TO AVOID AND MINIMISE IMPACTS

Table A-2 Commitments to avoid and minimise impacts under Sub-Plan A

Commitments	Actions	Timing
Commitment 2 Avoid and minimise impacts of up to 4,505 hectares of high biodiversity value area (the avoided land) through strategic conservation planning in the nominated areas. **Commitment 2.1** Limit cumulative direct impacts[1] over the life of the Plan from essential infrastructure to the following EPBC Act-listed threatened ecological community in the avoided land[2]: • Shale Sandstone Transition Forest • Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest • River-Flat Eucalypt Forest • Coastal Swamp Oak (Casuarina glauca) Forest • Cooks River Castlereagh Ironbark Forest Western Sydney Dry Rainforest and Moist Woodland on Shale **Commitment 2.2** Prioritise the avoidance of impacts from essential infrastructure on non-certified land to: • known populations[3] of the following threatened flora species:	1. Introduce an environmental planning instrument to apply development controls to protect important biodiversity on avoided land under the Plan. 2. Issue a Ministerial Direction under section 9.1 of the Environmental Planning and Assessment Act 1979 to restrict rezoning of avoided land from its current zone to a zone that permits a more intensive land use. 3. Introduce Cumberland Plain Conservation Plan Guidelines for Infrastructure Development to manage impacts on biodiversity from infrastructure development, including essential infrastructure development, on avoided land in the nominated areas. 4. Monitor the impacts of development on the avoided land through the Plan's reconciliation accounting process. 5. Notify proponents of essential infrastructure of their obligations under the EPBC Act, including when development does not have Part 10 EPBC Act approval under the Plan. 6. Locate Asset Protection Zones wholly within certified-urban capable land.	Actions 1,2,3: Before start of Plan Actions 4,5,6: Life of Plan as precincts are designed.

[1] Impact thresholds for each threatened ecological community per nominated area are listed in the Plan (Table 3, Cumberland Plain Conservation Plan, page 39).
[2] Distributions of these TECs are mapped in the *Cumberland Plain Assessment Report* and will require confirmation of extent through survey or assessment
[3] Known populations are mapped in the Cumberland Plain Assessment Report and will require confirmation of extent through survey or assessment

Commitments	Actions	Timing
○ *Grevillea parviflora* subsp. *parviflora* (Small-flower Grevillea) ○ *Persoonia bargoensis* (Bargo Geebung) ○ *Persoonia nutans* (Nodding Geebung) ○ *Genoplesium baueri* (Yellow Gnat-orchid) ○ *Pimelea spicata* (Spiked Rice-flower) ○ *Pultenaea parviflora* • protected koala habitat[4] within the Wilton and Greater Macarthur Growth Areas to maintain the function of koala movement corridors		
Commitment 3 Avoid and minimise impacts to threatened ecological communities, species and their habitat within certified-major transport corridors through detailed planning and design. This includes: • Avoiding areas of potential habitat[5] connectivity within riparian corridors where possible, particularly for the following species: ○ Eastern Pygmy Possum ○ Green and Golden Bell-Frog ○ Spotted-tailed Quoll ○ Squirrel Glider ○ Yellow-bellied Glider • Avoiding known flora populations[6] within the OSO and M7/Ropes Crossing Link Road	1. To avoid and minimise impacts to threatened ecological communities, species and their habitat Transport for NSW will apply the Plan's Avoidance Criteria during the strategic planning phase of each transport project with specific consideration to the matters identified in Commitment 3. 2. Include the biodiversity benefits of avoiding threatened ecological communities, species and their habitat as well as the costs of offsets into the evaluation of the route options (for example multi-criteria analysis). 3. Locate Asset Protection Zones, if required, within the certified-major transport corridor. 4. Where an action cannot feasibly or practically avoid impacts on an area of high environmental value, these impacts should be minimised as far as possible using design refinements to reduce overall impact. 5. Transport for NSW will provide to the department a Clearing Reconciliation Report within 60 days of the completion of clearing for each major transport corridor project. The Clearing Reconciliation Report will provide information on vegetation cleared, resulting direct impacts to threatened species habitat and threatened ecological communities, and a demonstration of	Life of Plan

[4] Protected koala habitat is mapped in the *Cumberland Plain Assessment Report* and the department's spatial viewer
[5] Potential habitat for fauna species are mapped in the *Cumberland Plain Assessment Report*
[6] Known flora populations are mapped in the *Cumberland Plain Assessment Report*

Commitments	Actions	Timing
corridors where possible, particularly: ○ *Dillwynia tenuifolia* ○ *Grevillea juniperina subs. juniperina* ○ *Pultanea parviflora* ○ *Persoonia nutans* • For the OSO, minimising where possible the placement of waterway crossing structures within riparian corridors, changes to waterway alignments, and bulk earthworks on adjacent floodplain areas	how the Plan's Avoidance Criteria were applied. The report will be used to: a. Inform the Plan's reconciliation accounting process to track impacts b. Determine Transport for NSWs actual offsets liability. Actual offsets liability will be reconciled against Transport for NSWs schedule of estimated forward payments for amounts outstanding or overpaid 6. Ensure that proponents of any Third Party Activities not included in the Western Sydney Major Transport Corridors class of action, are aware that they must consider the need for referral under the EPBC Act for actions likely to have a significant impact on MNES. 7. Impacts to biodiversity (including to MNES) in the major transport corridors will be published through the Plan's annual updates and five yearly reviews.	
Commitment 4 Avoid and minimise impacts on threatened ecological communities, species and their habitat within major transport corridors (strategically assessed only), including the Outer Sydney Orbital and Metro Rail Future Extension tunnel sections, in accordance with the: • Major transport corridors class of action description, including the NSW State Significant Infrastructure (or equivalent) approvals process • Biodiversity Assessment Method (BC Act) (or equivalent) **Commitment 4.1** This includes avoiding and minimising impacts to known flora populations[7] within the OSO and M7/Ropes Crossing Link Road corridors, including:	1. To avoid and minimise impacts to threatened ecological communities, species and their habitat Transport for NSW will: a. Undertake surveys to confirm biodiversity values, including matters of national environmental significance (MNES) during the strategic planning phase of each transport project b. Include the biodiversity benefits of avoiding threatened ecological communities, species and their habitat as well as the costs of offsets into the evaluation of the route options (for example multi-criteria analysis) c. Avoid and minimise impacts to biodiversity values, including MNES, in accordance with the Biodiversity Assessment Method (or equivalent) and with specific consideration to the protected matters identified in Commitments 4.1, 4.2 and 4.3 during the environmental impact assessment phase of each transport project. d. Offset impacts to biodiversity values, including MNES, in accordance with the Biodiversity Assessment Method (or equivalent) and EPBC Act Environmental Offsets Policy, 2012 for any EPBC Act matters not covered by the BAM. e. Report to the department and executive implementation committee on vegetation cleared and adjustments to transport corridor boundaries identified through the NSW SSI approval (or equivalent) for each transport project. This will include: reporting on	Life of Plan

[7] Known flora populations are mapped in the *Cumberland Plain Assessment Report* and will require confirmation of presence through survey or assessment

Commitments	Actions	Timing

• *Dillwynia tenuifolia*
• *Grevillea juniperina* subsp. *juniperina*
• *Pultenaea parviflora*
• *Cynanchum elegans*
Commitment 4.2
This includes avoiding and minimising impacts where possible within and adjacent to the tunnel sections, including:
• Known populations and habitat[8] of:
  o *Eucalyptus benthamii*
  o *Pomaderris brunnea*
  o *Pimelea spicata*
  o Cumberland Plain Land Snail
• Known populations and habitat, and threatened ecological communities[9] within:
  o Mater Dei BioBank site within the Outer Sydney Orbital footprint near Camden
  o Registered Property Agreement site within the Outer Sydney Orbital footprint at Camden Airport
  o Metro Offset site within the footprints for the Outer Sydney Orbital and Metro Rail Future Extension near Harrington Park
  o Nepean River and associated riparian
	avoidance achieved within the mapped or protected corridors identified in this plan; additional impacts outside of mapped corridors for EPBC act-listed species, populations or ecological communities; and offsets to be secured under the NSW SSI approval and EPBC Act Environmental Offsets Policy, 2012, where relevant
	2. The department will use this information to track impacts and adjust TfNSW's offset liabilities through the Plan's reconciliation accounting process, in agreement with TfNSW.
	3. Transport-related impacts to biodiversity (including MNES) will be published through the Plan's annual updates and five yearly reviews.	

[8] Known populations and habitat of listed species are mapped in the *Cumberland Plain Assessment Report* and will require confirmation of extent through survey or assessment. The Assessment Report includes a specific map as part of the assessment of tunnels (See the *Cumberland Plain Assessment Report*, Chapter 36.6)

[9] Known populations and habitat of listed species and distribution of listed TECs are mapped in the *Cumberland Plain Assessment Report* and will require confirmation of extent through survey or assessment. The Assessment Report includes a specific map as part of the assessment of tunnels (See the *Cumberland Plain Assessment Report*, Chapter 36.6)

Commitments	Actions	Timing
corridor within the Outer Sydney Orbital footprint ○ Camden Golf Club at Narellan adjacent to the footprint for the Metro Rail Future Extension ○ Mount Annan Botanic Gardens within the footprint for the Metro Rail Future Extension **Commitment 4.3** This includes avoiding and minimising impacts where possible to environmental values within Commonwealth Land sites[10], including known populations and habitat and threatened ecological communities, and existing infrastructure and services, at: • Camden Airport • Western Sydney University (Campbelltown Campus) • 12 Werombi Road, Grasmere NSW		

COMMITMENTS TO MITIGATE INDIRECT AND PRESCRIBED IMPACTS

Table A-3: Commitments to mitigate indirect and prescribed impacts under Sub-Plan A

Commitments	Actions	Timing
Commitment 5 Mitigate indirect and prescribed impacts from urban and industrial development; infrastructure; and intensive plant agriculture on threatened ecological communities, species and their habitat. This	1. Incorporate development controls in the State-led development control plans (DCPs) where State-led DCPs apply to relevant nominated areas, setting out development controls that need to be addressed by neighbourhood plans and development applications to mitigate indirect and prescribed impacts on threatened species. This includes: a. Specific controls that apply to the nominated areas to mitigate indirect and prescribed	Action 1: Before start of Plan Action 2: Year 1

[10] The Assessment Report includes a specific map as part of the assessment of tunnels (See the *Cumberland Plain Assessment Report*, Chapter 36.6)

Commitments	Actions	Timing
includes: • Meeting specific mitigation requirements for threatened ecological communities, species and their habitat in accordance with Appendix E of the Plan	impacts on specific threatened species or ecological communities or other environmentally sensitive areas in accordance with Appendix E of the Plan b. A common set of development controls to mitigate indirect and prescribed impacts across the four nominated areas that inform general biodiversity protection as listed in Chapter 15 of the Assessment Report. 2. Introduce Cumberland Plain Conservation Plan Mitigation Measures Guidelines (Mitigation Measures Guidelines) consistent with Appendix E of the Plan to address indirect impacts in Greater Macarthur Growth Area and Greater Penrith to Eastern Creek Investigation Area. 3. Provide ongoing support to local councils and other proponents in the application of DCP controls and Mitigation Measures Guidelines within the nominated areas, including the sharing of knowledge, maps and data. 4. Audit Growth Area Development Control Plans (DCPs), for the Plan's nominated areas where they apply, to ensure the Cumberland Plain Conservation Plan DCP Template development controls are incorporated in accordance with the DCP requirements for each Growth Area. 5. Monitor the implementation of the development controls through approval conditions by the relevant consent authority. If monitoring finds that development controls are not being effectively implemented, review and redraft new controls to update relevant State DCPs and Mitigation Measures Guidelines and re-educate councils to ensure stronger consideration of the controls through their assessment process. 6. Introduce the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development to be addressed by a public authority or other proponents of essential infrastructure, that includes mitigation measures for indirect and prescribed impacts to biodiversity from infrastructure activities in accordance with Appendix E of the Plan. 7. Implement mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the requirements of the NSW approval process, as well as published, best practice guidelines. 8. Consult with the relevant public land manager to minimise disturbance and impacts to threatened species in accordance with Appendix E, including: a. Ensuring walking tracks and management trails in Wianamatta Regional Park are located in a way that avoids and minimises exposure of Persoonia nutans to human disturbance b. Ensuring land management in potential habitat for *Pimelea spicata*, particularly mowing and slashing activities and weed management activities involving the use of herbicides, will minimise risks and maintain the species c. Work with NSW Fisheries to address the risk of illegal and incidental recreational fishing	Actions 3,4,5: Life of Plan Action 6: Year 1 Action 7: Life of Plan Action 8: Year 1-5

Commitments	Actions	Timing
	capture along stretches of known habitat for Macquarie Perch in Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River d. Installing signs and/or interpretive displays at appropriate sites in areas used for recreational fishing along Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River to assist with identification of Macquarie Perch and awareness of threats	
Commitment 6 Mitigate indirect and prescribed impacts on threatened ecological communities, species and their habitat within major transport corridors, including the Outer Sydney Orbital and Metro Rail Future Extension tunnel sections, in accordance with the: • Major transport corridors class of action description, including the NSW State Significant Infrastructure (or equivalent) approval for certified-major transport corridors • Major infrastructure corridors class of action description and the Biodiversity Assessment Method (BC Act) (or equivalent) for non-certified major transport corridors (strategically assessed) • Specific mitigation measures to address impacts on biodiversity values prescribed in Appendix E	1. To mitigate indirect and prescribed impacts on threatened species and their habitat Transport for NSW will, across all major transport corridors: a. Assess the impacts on biodiversity values (for non-certified major transport corridors) and other environmental values (for certified- and non-certified major transport corridors) based on detailed design b. Implement specific mitigation measures prescribed in Appendix E and identify and implement additional mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the requirements of the State Significant Infrastructure (or equivalent) approval process, as well as published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines c. Apply further mitigation according to the Biodiversity Assessment Method (BC act) (or equivalent) for non-certified major transport corridors (strategically assessed), including the tunnels sections d. Identify potential design options for major watercourse crossings to reduce disruption to connectivity and the risk of fauna vehicle strikes e. Establish baseline monitoring data and undertake ongoing monitoring of high-value environmental areas, and review and adjust mitigation measures (where practical) in response to monitoring outcomes, in accordance with the requirements of the State Significant Infrastructure (or equivalent) approval 2. Transport for NSW will report to the department and executive implementation committee on mitigation measures proposed to manage impacts of each major transport corridor project, including proposed techniques, timing, frequency and responsibility for implementing each measure.	Actions 1,2: Life of Plan
Commitment 7 Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in	1. Install koala exclusion fencing, including gates and grids, between koala habitat that can safely support koalas and urban land within the Greater Macarthur Growth Area and Wilton Growth Area, except where exclusion fencing is not feasible or necessary due to slope, heritage or water courses. a. Manage impacts to fences by locating koala exclusion fencing at least three metres from any trees where practical (measured from canopy)	Action 1: Life of Plan Action 2: Year 1 Action 3:

Commitments	Actions	Timing
accordance with Appendix E of the Plan.	b. Apply koala specific mitigation actions in accordance with Appendix E c. Where fencing must cross existing or planned linear infrastructure such as gas and electricity transmission, consider appropriate access treatments such as gates to ensure the integrity of the koala exclusion fencing d. Fence off koala corridors that are too narrow to safely support koalas and relocate koalas out of the unsafe corridors if needed. (Commitment 12 Action 1f) e. Address the requirements of the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development, as essential infrastructure for EPBC Act approval in the avoided land 2. Complete a feasibility study on the koala exclusion fencing to help inform the design, locations and construction of the fencing and identify fencing priorities for the first five years. 3. Install koala-exclusion fencing along the western alignment of the Georges River Koala Reserve where existing urban development is a threat to koalas. 4. Install koala-exclusion fencing, in the vicinity of koala habitat, along both sides of Appin Road between Rosemeadow and Appin, to mitigate koala vehicle strikes at roadkill hotspots. Fencing along Appin Rd will be in addition to planned fencing works to be delivered by Transport for NSW. 5. Undertake targeted stakeholder and community engagement to support the delivery of koala-exclusion fencing. 6. Establish a koala working group with representation from relevant government agencies to support implementation of the koala commitments and actions. The working group will support implementation of the koala sub-plan, by providing advice to inform: a. Alignment, staging, and design of the koala exclusion fencing and fauna crossing, including advice about providing appropriate koala movement corridors b. Priority locations and approach for koala habitat restoration c. Monitoring and evaluation of the plan's koala commitments, including providing advice to support adaptive management based on monitoring and evaluation data d. Community and stakeholder engagement for the koala conservation commitments and actions e. Research and management actions relating to koalas 7. Work with local councils, NPWS and OSL to ensure the threats posed by dogs on all public land that is identified as koala habitat protected under the Plan, are managed. a. For land that is not publicly accessible, this will include the installation of signs and/or	Years 1-20 Action 4: Years 1-5 Action 5: Years 1-3 Action 6: Before start of Plan Action 7: Life of Plan Action 8: Years 1-5

Commitments	Actions	Timing
	fences b. For land managed as a reserve or for recreation, this will be achieved by incorporating requirements in a relevant Plan of Management 8. Provide safe fauna crossings, based on current best practice design, across Appin Road and other linear infrastructure by: a. Installing a koala underpass culvert under Appin Road, near the intersection with Brian Road to support east-west koala movement from the Georges River to the Nepean River b. Augmenting the existing Kings Falls Bridge at the Georges River by constructing a bench adjacent to the bridge abutments, to allow dry passage for koalas (and other fauna) under Appin Road, supporting north–south koala movement from the Georges River Koala Reserve to the southern koala habitat c. Investigation options for enhancing koala movement across the Upper Canal d. Address the requirements of the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development, as essential infrastructure for EPBC Act approval in the avoided land	

CONSERVING FLORA, FAUNA AND HABITAT

Table A-4: Commitments and actions for conserving flora, fauna and habitat under Sub-Plan A

Commitments	Actions	Timing
Commitment 8 Protect a minimum of 5,325 hectares of native vegetation[11] in the Cumberland subregion to conserve biodiversity values in perpetuity in accordance with the conservation land selection steps which may require up to 11,900 hectares of conservation land. **Commitment 8.1** This target includes minimum areas of the following EPBC Act-listed threatened ecological communities: • 675 hectares of Shale Sandstone Transition Forest • 665 hectares of Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest • 570 hectares of River-flat eucalypt forest of eastern Australia • 125 hectares of Cooks River Castlereagh Ironbark Forest • 20 hectares of Coastal Swamp Oak Forest • 0.2 hectares of Western Sydney Dry Rainforest and Moist Woodland on Shale **Commitment 8.2** This target includes minimum areas of the following BC Act-listed threatened ecological	1. Prepare a Conservation Land Implementation Strategy to guide the establishment of land for conservation, including: a. Priorities for selecting and purchasing land b. Targets and proposed timeframes for establishing new conservation land c. Proposed land-based conservation type for each area of priority conservation land (reserve or biodiversity stewardship agreement) d. Suitable land managers for each area of priority conservation land e. A process to secure alternative areas where targets and timing cannot be met 2. Enter into written agreements with delivery partners to set out the arrangements for conservation land under the Plan, including: a. Roles and responsibilities b. Processes for implementation c. Land management arrangements, including prior to purchase d. Funding arrangements e. Progress reporting 3. Seek to include the strategic conservation area (excluding cleared areas) in the Biodiversity Values (BV) Map. 4. Undertake surveys within the strategic conservation area or other avoided land prior to protecting the land to confirm plant community extent and condition and update vegetation mapping if necessary. 5. Protect and manage land containing targeted plant communities within the strategic conservation area by: a. Establishing reserves under relevant legislation including the National Parks and Wildlife Act 1974, Crown Land Management Act 2016, and Local Government Act 1993	Action 1,2: Year 1 Actions 3: Year 1 Action 4,5,6,7: Life of Plan Action 8: Before start of Plan Action 9,10,11: Life of Plan

[11] While there is overlap between the TEC targets listed in commitments 8.1 and 8.2, there are differences in the listings between EPBC Act-listed and BC Act-listed TECs, such as differences in approach and criteria. Therefore, the BC Act-listed TECs in commitment 7.2 incorporate targets for EPBC Act-listed TECs.

Commitments	Actions	Timing
communities: • 2,885 hectares of Cumberland Plain Woodland • 1,455 hectares of Shale Sandstone Transition Forest • 505 hectares of River-Flat Eucalypt Forest • 285 hectares of Shale Gravel Transition Forest • 115 hectares of Cooks River Castlereagh Ironbark Forest • 70 hectares of Swamp Oak Floodplain Forest • 10 hectares of Freshwater Wetlands on Coastal Floodplains • 0.2 hectares of Moist Shale Woodland	b. Establishing Biodiversity Stewardship Agreements under the Biodiversity Conservation Act 2016 c. Purchasing and retiring biodiversity credits under the Biodiversity Offsets Scheme (BOS) 6. Track the progress of meeting threatened ecological community targets (in hectares) through the reconciliation accounting process (Commitment 25 Action 2). 7. Provide upfront funding for business cases and Biodiversity Assessment Method assessments to support landholders entering into biodiversity stewardship agreements, where this investment can be recouped through the later sale of biodiversity credits. 8. Define a land purchase strategy that will guide decision-making and processes to be used when purchasing land for conservation under the Plan. 9. Purchase land within the strategic conservation area to commence establishing reserves under the Plan with priority given to land listed for sale and land in the proposed Koala Reserve. 10. Introduce an acquisition clause in an environmental planning instrument to land identified for future reserves under the Plan as funds become available through the program. 11. Work with local councils and other land managers to ensure that reserves established under the Plan provide for increased public access, including the provision of compatible low biodiversity impact recreation activities.	
Commitment 9 Protect threatened species likely to be at risk of residual adverse impacts from development under the Plan (target species) in accordance with the Plan's conservation land selection steps. This includes securing offsets to protect known locations for the following target threatened species: Flora species • 2 offset locations for *Cynanchum elegans* • 3 offset locations for *Dillwynia tenuifolia* • 3 offset locations for *Grevillea juniperina* subsp. *juniperina* • 1 offset location for *Hibbertia fumana* • 1 offset location for *Hibbertia puberula* • 2 offset locations for *Marsdenia viridiflora* subsp.	1. Assess and record the habitat attributes of where target species have been located and use the information to establish baseline monitoring data for areas of known habitat for target species and incorporate into the evaluation program (Commitment 25). 2. Protect offset locations and species habitat for the target threatened species through establishing reserves or biodiversity stewardship sites or through the direct purchase of species credits in the Cumberland subregion or across NSW. 3. Achieve the Plan's species targets by applying the conservation land selection steps. 4. Identify species-specific management measures for areas of known habitat for target species, in consultation with future land managers of reserves established under the Plan and incorporate these into management plans for the land. 5. Track progress in meeting species offset targets through the reconciliation accounting process (Commitment 25 Action 2).	Action 1: Year 1 Action 2,3,4,5: Life of Plan

Commitments	Actions	Timing
viridiflora • 2 offset locations for *Persoonia nutans* • 3 offset locations for *Pimelea spicata* • 2 offset locations for *Pultenaea parviflora* • 2 offset locations for *Pultenaea pedunculata* Fauna species • 1 offset location for *Haliaeetus leucogaster* • 1 offset location for *Hieraaetus morphnoides* • 1 offset location for *Lophoictinia isura* • 3 offset locations for *Meridolum corneovirens* • 1 offset locations for *Myotis macropus* And habitat for the following target threatened fauna species: • 4,410 hectares of potential foraging habitat for *Lathamus discolour* (including 100ha of *Lathamus discolour* important habitat as defined under the BAM) • 570 hectares of important habitat[12] for *Phascolarctos cinereus* as defined in the Cumberland Plain Assessment Report.		
Commitment 10 Establish a reserve to protect the north-south koala movement corridor along the Georges River between Appin and Long Point.	1. Transfer and reserve lots identified for early transfer to National Parks and Wildlife Service as the first stage in establishing Georges River Koala Reserve. 2. Reserve additional areas of the Georges River Koala Reserve between Appin and Kentlyn using NSW government land as a priority and by purchasing additional land (Stages 1a and 1b). 3. Reserve additional areas of the Georges River Koala Reserve between Kentlyn and Long Point using NSW government land as a priority and by purchasing additional land (Stage 2). 4. Restore up to 80 hectares of cleared land for koala habitat in priority areas including the Georges	Action 1: Years 1-2 Action 2: Years 1-10 Action 3: Years 1-20 Action 4:

[12] Important koala habitat is the term used to describe primary, secondary and tertiary corridors, as defined in the *Cumberland Plain Assessment Report*. It is the area that is critical to the long-term viability of koalas (primary corridors) as well as the areas (if enhanced) that would support the population (secondary and tertiary corridors).

Commitments	Actions	Timing
	River Koala Reserve to strengthen the north-south koala corridor. 5. Restore additional koala habitat within the Georges River Koala Reserve to strengthen the north-south koala movement corridor. 6. Work with NPWS, OSL and other key stakeholders to prepare a concept plan for the Georges River Koala Reserve.	Years 1-5 Action 5: Years 6-25 Action 6: Year 1
Commitment 11 Establish at least two new reserves in addition to the Georges River Koala Reserve that will protect threatened communities, species and habitat that are targeted for protection through the Plan.	1. Investigate a new reserve that will provide an ecological connection between Gulguer Nature Reserve, Bents Basin State Conservation Area and Burragorang State Conservation Area. 2. Investigate a new reserve on Wianamatta (South Creek) that will allow for the restoration of up to 370 hectares of threatened ecological communities. 3. Establish a community engagement program with landholders in the reserve investigation areas to provide information and seek expressions of interest for land purchase to support establishment of new reserves. 4. Establish biodiversity stewardship agreements appropriate on land purchased for a future reserve to commence management of the site. 5. Gazette at least two new reserves in addition to the Georges River Koala Reserve by Year 20 of the Plan.	Action 1,2: Year 1 Action 3: Years 1-10 Action 4: Life of Plan Action 5: Year 1-20
Commitment 12 Protect koala corridors in the Cumberland subregion, including those along the Nepean River, Georges River, Cataract River and Ousedale Creek.	1. Apply development controls to koala habitat protected under the Plan and ensure safe, functional corridors for koala movement (consistent with advice from the Office of the NSW Chief Scientist & Engineer) including: a. The north-south koala corridor along the Georges River (Commitment 10) b. The north-south koala corridor along the Nepean and Cataract rivers c. The east-west corridor along Ousedale Creek between the Georges River and Nepean River d. Elladale Creek and Simpsons Creek as an area of functional koala habitat. e. The north-south koala corridor along Allens Creek f. Excluding koalas from east-west corridors that do not meet the minimum requirements for a functional koala corridor (Corridor C: Nepean Creek to Beulah, and Corridor D: Mallaty Creek to Georges River) 2. Restore koala habitat in the Georges River and Ousedale Creek corridors to ensure they meet requirements for safe and functional koala movement corridors, consistent with advice from the Office of the NSW Chief Scientist & Engineer (Commitment 13).	Action 1: Before start of Plan Action 2: Life of Plan

Commitments	Actions	Timing
Commitment 13 Deliver and support ecological restoration activities in conservation land including ecological reconstruction of up to a maximum of 25% of the Plan's offset target for native vegetation (Commitment 8).	1. Establish a Restoration working group to guide the implementation of restoration activities under the Plan including the preparation of a Restoration Implementation Strategy and supporting technical guidance where relevant. 2. Develop a Restoration Implementation Strategy in consultation with the Restoration working group and other key stakeholders to establish best practice principles and methodologies, to: a. Identify the range of restoration activities and what will be undertaken under the Plan b. Ensure the long-term sustainability of restoration considers genetic diversity in what is established c. Identify considerations for restoration potential and constraints of land d. Provide reference to guidelines for restoration, including the NSW BCT Guidelines for restoring native vegetation undertaken in a biodiversity stewardship site e. Develop a seed-procurement approach f. Reference research needs being considered through the Research Program Implementation Strategy (Commitment 22, Action 1) g. Enter into written agreements with delivery partners and engage specialist providers where necessary to implement the restoration actions. 3. Deliver ecological restoration (including reconstruction) to restore koala habitat in the Georges River Koala Reserve and other priority locations in the strategic conservation area including along Ousedale Creek and around Appin. 4. Incorporate adaptive management principles into restoration actions including pilot sites to trial and develop restoration methodologies and applying new research as appropriate. 5. Deliver up to a maximum of 1,330 hectares of ecological reconstruction on conservation land targeting the following threatened ecological communities: a. Cooks River Castlereagh Ironbark Forest b. Cumberland Plain Woodland c. River-flat Eucalypt Forest d. Shale Gravel Transition Forest e. Swamp Oak Forest	Action 1,2: Year 1 Action 3: Year 1 onwards Action 4: Life of Plan Action 5: Years 1-3 Action 6: Life of Plan
Commitment 14 Minimise impacts from development on biodiversity values in the strategic conservation area.	1. Introduce a State Environmental Planning Policy to apply development controls to the strategic conservation area to require consideration of impacts on biodiversity values when consent authorities assess development applications. 2. Issue a Ministerial Direction under section 9.1 of the Environmental Planning and Assessment Act	Actions 1,2: Before start of Plan Action 3:

Commitments	Actions	Timing
	1979 (NSW) to require consistency with the objectives of the strategic conservation area when a planning authority prepares a planning proposal or reviews Local Environmental Plans within the strategic conservation area. 3. Work with local councils to integrate mapping of the strategic conservation area into local and regional planning through Local Strategic Planning Statements, which guide the local plan-making process.	Life of the Plan

MANAGING LANDSCAPE THREATS

Table A-5: Commitments and actions to manage landscape threats under Sub-Plan A

Commitments	Actions	Timing
Commitment 15 Manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the strategic conservation area.	1. Participate in the Sydney Weeds Network to inform the implementation of weed control activities under the Plan including the preparation of a Weed Control Strategy. 2. Prepare a Weed Control Strategy, in consultation with the Sydney Weeds Network to establish a coordinated weed control program in the Cumberland subregion, that: a. Identifies priority weed species and priority locations for weed control to maximise benefits to biodiversity in the strategic conservation area b. Identifies the training, extension and resource needs to address threats c. Provides guidance on weed control methods d. Identifies roles, responsibilities, delivery partners and other stakeholders e. Provides guidance on funding decisions under the weed control program f. Is consistent with existing weed control programs, reserve or BSA management requirements 3. Enter into written agreements with delivery partners to implement the Weed Control Strategy. 4. Integrate weed control actions for conservation land into reserve management plans. 5. Fund organisations to help deliver actions in the Weed Control Strategy for example Bushcare and Landcare groups, and Local Aboriginal Land Councils.	Action 1: Year 1 Actions 2,3: Year 2 Action 4: Life of Plan Action 5: Year 3 onwards
Commitment 16 Manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected within the strategic conservation area.	1. Establish a Pest Animal Control working group to guide the implementation of pest animal control activities under the Plan including preparation of a Pest Animal Control Implementation Strategy. 2. Prepare a Pest Animal Control Strategy to guide the implementation of the pest control program, that: a. Identifies pest control priorities, including priority pest species and priority locations for pest control to maximise benefits to biodiversity in the strategic conservation area b. Identifies the training, extension and resource needs to address threats c. Provides guidance on pest control methods d. Identifies roles, responsibilities delivery partners and other stakeholders e. Provides guidance on funding arrangements under the pest control program f. Is consistent with existing pest control programs, reserve or BSA management requirements 3. Ensure that the Pest Animal Control Strategy specifies the use of pest control techniques that will reduce the risk of secondary poisoning from Pindone or second-generation rodenticides in accordance with Appendix E.	Action 1: Year 1 Actions 2,3,4: Year 2 Action 5: Year 3 onwards

Commitments	Actions	Timing
	4. Enter into written agreements with delivery partners to implement the pest animal control program. 5. Fund organisations to help deliver actions in the Pest Animal Control Strategy for example Greater Sydney Local Land Care Services, Bushcare and Landcare groups, and Local Aboriginal Land Councils.	
Commitment 17 Manage fire in strategic locations in the Cumberland subregion to support the maintenance of biodiversity values on conservation land.	1. Consult with the NSW Rural Fire Service, NSW National Parks and Wildlife Service, and the department (Environment, Energy and Science Group) to identify fire management priorities, including fire sensitive species and ecological communities. 2. Partner with Aboriginal knowledge holders and organisations to learn about Indigenous fire management techniques and consider how this knowledge may be applied to manage and protect conservation land. 3. Prepare a Fire Management Strategy, that: a. Identifies priority locations for fire management to maximise benefits to biodiversity in the strategic conservation area b. Identifies priority fire-sensitive species and ecological communities c. Provides guidance on fire management to maintain and promote biodiversity values, particularly among fire sensitive species and ecological communities d. Identifies roles and responsibilities and co-ordinates delivery partners e. Provides criteria to guide decisions on funding of fire management under the Plan 4. Enter into written agreements with delivery partners to implement the Fire Management Strategy. 5. Integrate fire management actions for conservation land identified in the Fire Management Strategy in stewardship agreements and reserve management plans.	Actions 1-4: Year 2 Action 5: Year 3 onwards
Commitment 18 Support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion.	1. Consult with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion including consideration of the following key threatening processes: a. *Phytophthora cinnamomi* root fungus b. Amphibian chytrid fungus c. Psittacine circoviral beak and feather disease d. Psyllid and Bell Miner associated dieback in Eucalypts 2. Enter into written agreements with delivery partners to implement priority disease control programs. 3. Require regular reporting by delivery partners on the disease control program outcomes to the department and to the executive implementation committee.	Actions 1,2,3: Year 6 onwards

Commitments	Actions	Timing
Commitment 19 Support existing or new programs to help threatened species and ecological communities adapt to the impacts of climate change in the Plan Area.	1. Consider funding research on climate change adaptation in developing the Research Program Implementation Strategy (Commitment 22, Action 1). 2. Partner with the Royal Botanic Gardens Greater Sydney to develop seed sourcing guidelines for ten keystone Cumberland Plain Woodland species and define the species-specific seed transfer zones for these species. 3. Update the strategic conservation area if new priority locations are identified through research that will support biodiversity adaptation to climate impacts and incorporate these new areas into the Conservation Land Implementation Strategy (Commitment 8).	Action 1: Year 1 Action 2: Years 1-3 Action 3: Every 5 years

BUILDING KNOWLEDGE AND CAPACITY

Table A-6: Commitments and actions to build knowledge and capacity under Sub-Plan A

Commitments	Actions	Timing
Commitment 20 Provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation including koala conservation.	1. Prepare an Education and Engagement Implementation Strategy to guide implementation of the education and engagement program, that: a. Identifies priority topics for education b. Identifies intended audiences c. Proposes implementation mechanisms d. Outlines governance arrangements for implementing the program 2. Establish three full-time community engagement officers to work across the local councils in the Plan Area to: a. Undertake activities according to the Education and Engagement Implementation Strategy and monitor its implementation b. Support biodiversity programs that are consistent with the objectives of the Plan c. Coordinate activities and pop-up events d. Coordinate grants to local councils and community groups for projects that meet criteria developed in the Strategy 3. Fund local councils and community groups to help deliver an education and engagement program that is consistent with the Education and Engagement Implementation Strategy, with indicative activities that include: a. Engaging with local schools to provide biodiversity education b. Hosting community activities such as tree planting and nature walks c. Developing a mobile education trailer as a shared resource for local councils in the plan area d. Promoting new and existing citizen science programs to encourage participation in nature-related science e. Raising awareness of the cultural significance of biodiversity to Aboriginal people 4. Invest in the NSW Koala Strategy to raise awareness of the Southern Sydney koala population and encourage community participation in koala conservation in Western Sydney. 5. In partnership with the Biodiversity Conservation Trust establish a community engagement program to educate landholders within the strategic conservation area and promote the opportunities and benefits of biodiversity stewardship sites. 6. Work with councils and other landholders to install signs and interpretive displays at identified	Action 1: Year 4 Action 2: Year 5 Action 3: Year 5 onwards Action 4: Year 1 onwards Action 5: Year 1 Action 6: Life of the Plan

Commitments	Actions	Timing
	conservation land to raise awareness of the biodiversity values of a site.	
Commitment 21 Partner with Aboriginal groups and community to help maintain a distinctive cultural, spiritual, physical and economic relationships with their land and waters in Western Sydney	1. Fund a grants program to build capacity in the three LALCs in the Plan Area to fund land management and biodiversity works, and culture and heritage projects on Aboriginal-owned lands and other important areas. 2. Partner with Aboriginal community such as Traditional Custodians, Aboriginal Land Councils and other interested Aboriginal people in Western Sydney to collaboratively develop a 10-year Aboriginal Engagement and Implementation Strategy. 3. Partner with Western Sydney's Aboriginal community to implement the Plan and a 10-year Aboriginal Engagement and Implementation Strategy through: a. Establishing partnerships, including the co-design of actions under the Strategy, with Traditional Custodians, Aboriginal Land Councils, Aboriginal businesses and other interested Aboriginal groups b. Establishing an Aboriginal advisory group to provide advice on the delivery of the Aboriginal Engagement and Implementation Strategy and the Plan c. Actively engage and empower Aboriginal groups and community to enable participation in decision making to deliver the Aboriginal Engagement and Implementation Strategy and the Plan 4. Implement a 10-year Aboriginal Engagement and Implementation Strategy to support economic participation for Aboriginal people and cultural outcomes under the Plan to: a. Recognise, celebrate and promote Aboriginal culture and heritage in Western Sydney with a focus on natural areas and protecting biodiversity b. Recognise and embed the knowledge and connection that Aboriginal people have with Country c. Enable traditional custodians and interested Aboriginal groups to care for Country on new conservation land d. Grow Aboriginal businesses and employment in the environmental sector	Action 1: Year 1-2 Action 2: Year 1 Action 3,4: Years 2-11 Action 5: Year 5 onwards
Commitment 22 Invest in research priorities that will support the implementation of the Plan and help to deliver the Plan's outcomes.	1. Develop a Research Program Implementation Strategy to guide delivery of a 35-year research program that will help achieve the Plan's outcomes in Western Sydney, including identifying research priorities for the first four years of the program. 2. Deliver a research program in accordance with the Research Program Implementation Strategy. The research program may include: a. Research on the vulnerability of threatened species and ecological communities to climate change	Action 1: Year 1 Action 2: Year 2 onwards

Commitments	Actions	Timing
	b. Research that increases knowledge of the adaptive capacity of plant, animal and microbial organisms used in active restoration of ecological communities of the sub-region c. Research that improves restoration outcomes, including ecosystem function and resilience, for threatened ecological communities of the sub-region d. Research on ecological connectivity and landscape function at site, local and regional scales to enhance conservation outcomes e. Research into changing community attitudes and behaviour to biodiversity and conservation values including factors influencing those and how they evolve and change f. Research into the connections between land management, biodiversity and aboriginal culture and practices in Western Sydney as proposed by the Aboriginal Engagement and Implementation Strategy (Commitment 21) 3. Support NSW Government programs for threatened species research in Western Sydney including: a. Research on threatened species impacted by the Plan in the Cumberland subregion through the Saving our Species program b. Research that increases knowledge of population demographics, life-history and ecology of the Southern Sydney koala population, as part of the NSW Koala Strategy's NSW Koala Research Plan	
Commitment 23 Support rehabilitation measures to help maintain koala health and welfare.	1. Invest in the *NSW Koala Strategy* and other potential partners to implement the koala health and welfare program in South Western Sydney with key deliverables including: a. Monitoring of koalas including key threats and effectiveness of mitigation measures as part of the NSW Koala Strategy Monitoring Framework b. Designating the koalas in South Western Sydney as one of the dedicated monitoring sites for the NSW Koala Strategy c. Providing enhanced training in wildlife treatment for veterinarians d. Providing grants for community wildlife organisations for resources and carer recruitment and training e. Establishing health and welfare programs to support koalas from threats including vehicle strike, fire, disease and climate change 2. Koalas that are captured and/or handled as part of a monitoring program will be vaccinated against chlamydia and have a tissue sample taken for genetic analysis, with the tissue samples lodged with the NSW Koala Biobank.	Action 1,2: Year 1 onwards

GOVERNANCE AND REPORTING

Table A-7: Commitments and actions for governance and reporting under Sub-Plan A

Commitments	Actions	Timing
Commitment 24 Establish governance arrangements including roles, responsibilities, and funding to ensure the efficient and effective implementation of the Plan.	1. Establish a multi-agency executive implementation committee to act as a central governance steering committee for the Plan. 2. Enter into written agreements with delivery partners, including Transport for NSW as project partner responsible for delivering the major transport corridors to support the implementation of specific commitments and actions. 3. Establish working groups to advise the executive implementation committee and oversee implementation of specific commitments and actions (commitments 7, 13, 16 and 26). 4. Establish arrangements to fund delivery of the Plan's commitments and actions through contributions from residential, commercial and industrial developers in the nominated areas. 5. Ensure that at least 90% of conservation program funding is spent on establishing and restoring conservation land or purchasing biodiversity credits consistent with the conservation land selection steps.	Actions 1-7: Year 1 Action 8: Life of Plan
Commitment 25 Implement an evaluation program for the Plan that sets out requirements for monitoring, evaluation, reporting and adaptive management.	1. Finalise the evaluation program in consultation with key stakeholders, including: a. Establishing governance arrangements for the evaluation program as part of the Plan's governance arrangements for implementation b. Establishing a monitoring and data collection methodology c. Finalising evaluation questions including scope and frequency d. Developing a method for evaluation outputs to support adaptive management e. Establishing the reconciliation accounting process to track progress of the Plan's commitments and actions f. Developing templates for reporting quarterly to the executive implementation steering committee and annual updates over the life of the Plan. g. Establishing processes to support independent five-yearly reviews of the Plan 2. Track progress of meeting conservation targets in hectares through the reconciliation accounting process 3. Implement adaptive management steps for offsets if the reconciliation accounting process determines that the Plan's offsets are not keeping track with development. 4. Publish annual updates on implementation of the Plan. 5. Undertake independent five-yearly reviews of the progress of the Plan, including progress towards	Actions 1: Year 1 Action 2,3,4,5: Life of the Plan Action 6: Year 1 onwards

Commitments	Actions	Timing
	meeting commitments and achieving outcomes, and publish a review report. 6. Undertake internal process reviews at the mid-term point (2.5 years) between independent reviews and provide to key delivery partners and stakeholders. 7. Develop an overarching Communication and Engagement Strategy to support the Plan's implementation. This would be reviewed every 5 years and updated accordingly.	
Commitment 26 Implement a compliance program to ensure compliance with the Plan and conditions of approval.	1. Establish a Compliance and Implementation working group comprising the department, local councils and other relevant stakeholders to guide the implementation of compliance activities under the Plan including preparation of a Compliance Strategy. 2. Prepare a Compliance Strategy under guidance of the working group to: a. Identify relevant compliance mechanisms b. Set out compliance monitoring and auditing priorities and processes c. Set out a decision-making framework for taking compliance action d. Set out procedures and protocols for taking compliance action e. Identify roles and responsibilities for compliance 3. Provide funding to employ six full-time compliance officers to work with local councils to carry out compliance activities in the Plan Area. 4. Share knowledge, maps and data and provide ongoing support and training to council staff to assist local councils with carrying out implementation and compliance activities. 5. Publish a compliance report as part of the yearly update on implementation of the Plan and provide to local councils for review and investigation. 6. Prepare reports every two and a half years on any identified breaches with Plan commitments and approval conditions e.g. auditing development consent conditions, environmental management plans etc.	Actions 1,2: Year 1 Action 3: Year 2 onwards Action 4,5,6: Life of Plan

CUMBERLAND PLAIN ASSESSMENT REPORT

PART 3: ASSESSMENT APPROACH AND METHODS

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

DOCUMENT TRACKING

PREPARED BY:	
DATA:	James Shepherd, Callan Wharfe, Rebecca Dwyer, Matthew Hyde (Biosis)
CONTENT:	Callan Wharfe, Jane Raithby-Veall, Rebecca Dwyer (Biosis) Darren James (DAJ Environmental) Tom Holden, Peter Hemphill, Heather Tolley, Natasha Buckingham, Stephanie Binks, Heidi Birkby, Christa Shen (Open Lines)
REVIEWED BY:	
OPEN LINES:	Darren James (DAJ Environmental), Tom Holden and Peter Hemphill (Open Lines)
ACCREDITED ASSESSOR:	Jane Raithby-Veall (Biosis) BAM Assessor – BAAS18134
VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 3 Contents

Part 3 List of Tables

This Part sets out the approach and methods used to prepare the Assessment Report:

- Chapter 10: Provides an overview of the assessment approach
- Chapter 11: Describes the approach and methods for understanding the biodiversity values and other matters that require assessment within the Plan Area
- Chapter 12: Identifies where the approaches to assessing the impacts of the development under the Plan are described in the Assessment Report
- Chapter 13: Provides an overview of the data used in the Assessment Report and the limitations with the data

10 Overview

This Chapter sets out:

- An overview of the scope of the assessment
- A summary of the Biodiversity Assessment Method (BAM) that applies to the Biodiversity Certification Assessment Report (BCAR) and the Terms of Reference that applies to the Strategic Assessment Report (SAR)
- A discussion of the key steps in the assessment process
- An overview of the peer review processes for key methods

10.1 SCOPE

The scope of the assessments under the BC Act and EPBC Act are different (see Part 1). This relates to both:

- The development that is being assessed for approval
- The impact assessment requirements under each piece of legislation

The assessment approach was designed to meet the requirements of the assessment processes under both the BC Act and EPBC Act (see Table 10-1), as well as address the various overlaps and differences.

Table 10-1: Impact assessment requirements of the BC Act and the EPBC Act*

Legislation	Impact assessment requirements	Comments
BC Act	Relevant provisions of the legislation and regulations	The Cumberland Plain Conservation Plan (the Plan) is being assessed as a strategic application for biodiversity certification under Part 8 of the BC Act. The relevant regulatory provisions need to be met
	BAM	The BAM specifies the requirements for the BCAR
	Conservation measures in strategic applications for biodiversity certification (DPIE, 2020a)	The purpose of the DPIE strategic application guidelines is to help planning authorities preparing applications for strategic biodiversity certification 'demonstrate that proposed conservation measures adequately address the likely impacts on biodiversity values of the biodiversity certification of the land'. The guidelines must be addressed in the BCAR
EPBC Act	Relevant provisions of the legislation and regulations	The Plan is undergoing strategic assessment under Part 10 of the EPBC Act. The relevant regulatory provisions need to be addressed in the SAR
	Terms of Reference (ToR) for the SAR	The ToR specify the requirements for the SAR
	Relevant statutory documents	The EPBC Act requires that certain statutory documents be considered in the impact assessment process. For example, these include recovery plans, threat abatement plans, and conservation advices

Legislation	Impact assessment requirements	Comments
	EPBC Act policies and guidelines	The Australian Government has published a range of EPBC Act policies and guidelines which need to be considered in the impact assessment process

* See Part 1 for detail on the regulatory context of this project

10.2 BIODIVERSITY ASSESSMENT METHOD

The BAM was established under the BC Act to assess impacts on NSW listed threatened species and ecological communities and their habitats. As outlined on the Environment Energy and Science (EES) website:

> *"*[The BAM] *is a scientific document that provides:*
>
> - *a consistent method for the assessment of biodiversity on a proposed development or major project, or clearing site,*
> - *guidance on how a proponent can avoid and minimise potential biodiversity impacts, and*
> - *the number and class of biodiversity credits that need to be offset to achieve a standard of 'no net loss' of biodiversity."*

The BAM specifies the assessment requirements for the BCAR and was applied within the nominated areas.

The BAM also provides a strong starting point for meeting the EPBC Act ToR. For example, the detailed requirements around data gathering within the nominated areas are also largely appropriate for protected matters.

The BAM is structured around three stages:

- **Stage 1 – Biodiversity assessment**. This stage establishes a consistent approach to identifying and assessing the biodiversity values on land (including the land to be biodiversity certified). It sets out the data gathering requirements for the landscape context, native vegetation, and threatened species
- **Stage 2 – Impact assessment**. This stage provides the method for assessing impacts to biodiversity values. It specifies requirements around:
  - Avoiding and minimising impacts
  - Assessing both direct and indirect impacts
  - Dealing with issues such as prescribed impacts, and serious and irreversible impacts
  - Determining the credits required for meeting the no net loss standard
- **Stage 3 – Improving biodiversity values**. This stage is used to determine the credits that can be created at stewardship sites. This stage does not need to be applied at the time of application for strategic biodiversity certification and has therefore not been applied in this Assessment Report (see Chapter 2)

The outputs of the BAM for this project need to be presented in a BCAR. The components of this Assessment Report that comprise the BCAR are set out in Part 1.

The current version of the BAM came into force on 22 October 2020. The Assessment Report is operating under transitional arrangements and is prepared in accordance with the 2017 version of the BAM. The transitional arrangements are provided under clause 6.31 of the BC Regulation 2017 and allow this project to continue operating under the 2017 BAM for a period of 12 months since the change to the new BAM or 'such longer period as the Minister approves in a particular case'. The Environment Minister (through a delegated authority) has approved an extension to the transitional arrangements for the BAM that apply to this project to April 2022.

10.3 EPBC ACT TERMS OF REFERENCE

The ToR for the SAR are part of the Strategic Assessment Agreement between the NSW Government and Australian Government. The ToR set out the information requirements that this Assessment Report needs to address for matters protected under the EPBC Act.

Clause 4.2 of the ToR outlines how the Assessment Report should describe the methods used in the assessment:

> *"The Report must describe the method used to understand likely impacts on all protected matters of actions taken under the Plan. The level of the assessment will be proportionate to the level of likely risk to each protected matter. The method must:*
>
> 1. *Be appropriate for assessment at a strategic scale*
> 2. *Rely on the best available information*
> 3. *Discuss uncertainty, including reference to the technical data and information relied upon*
>
> *The Report must identify the data used in the assessment, any limitations it may have, where (or if) the data is available and where it can be accessed, including publicly accessed."*

The ToR specifies the assessment requirements for the SAR and was applied within the Plan Area. The ToR are provided in Supporting Document A.

10.4 PEER REVIEW OF KEY METHODS

Section 4.8 of the ToR for the SAR specifies:

> *"The Report must include justification for key methods used in the assessment, including summaries of independent peer review processes and where the review/s are available to the public."*

The term 'key methods' refers to technical methods for describing the protected matters impacted by the Plan, such as methods used to collect data on protected matters and map the location of protected matters.

The term does not include approaches to understand the likely impacts on protected matters of actions taken under the Plan, such as the approach to assessing direct, indirect and cumulative impacts.

In accordance with section 4.2 of the ToR, the SAR has described these impact assessment approaches in detail and any uncertainties or limitations with them (see Chapter 12 and Chapter 13).

The NSW Department of Planning, Industry, and Environment (the Department) commissioned an independent peer reviewer, Dr Rhidian Harrington, from Niche Environment and Heritage, to review the key methods. The key methods reviewed were:

- The approach to determining the relevant EPBC matters for assessment (see Section 11.1.2)
- The methodology for mapping EPBC listed TECs (see Section 11.4.3)
- The method for identifying important populations of flora and fauna (see Section 11.5.3)
- The approach and criteria for mapping habitat across the Cumberland subregion for approximately 30 threatened species using an expert knowledge-based process (see Section 11.5)
- An evaluation method for determining the viability of the Southern Sydney koala population (see Chapter 30)

The peer review process involved:

- Initial review of key methods by peer-reviewer
- One day workshop with ecological consulting team, technical staff from the Department and peer reviewer to discuss key methods
- Preparation of report that:
    - Sets out the context of the peer review (including expertise of the peer reviewer)
    - Analyses each method against the following questions:
        - Is the general approach to the method appropriate?
        - Are the details of the method appropriate?
        - Are there critical components of the method that need improvement?

The peer review report is provided in Supporting Document B.

The peer review report concluded that in general:

- The datasets, methods for data collection and assumptions associated with the methods are appropriate for a large-scale strategic assessment process such as this project
- The methods used are generally conservative and are unlikely to under-represent the presence or distribution of any TEC or species, and are more likely to over-predict presence and distributions

The report recommended that further details associated with the input data and assumptions be provided in the Assessment Report to provide the regulators and the public more complete understanding of limitations.

The limitations associated with the methods are set out in Chapter 13.

Several other methods were used to prepare the SAR. These methods and a rationale for not undertaking a peer review of them is provided in Table 10-2.

Table 10-2: Rationale for not undertaking peer review of other methods

Method	Rationale
Data collection and surveys for EPBC listed TECs and species	Data collection within the nominated areas was undertaken in accordance with the BAM. The BAM was independently peer reviewed in 2015. The previous formalised biodiversity assessment method – the BioBanking Assessment Method – was also independently reviewed
Species Distribution Modelling for Commonwealth-listed species	The Species Distribution Modelling work was undertaken by a Senior Research Fellow at RMIT University. The modelling process is a well-recognised and peer reviewed method for mapping species habitat at a landscape scale. References to published literature establishing the validity of the method are provided in the Species Distribution Modelling Report (see Supporting Document F) Species experts at EES reviewed several example outputs of the model and provided input into the modelling method
Migratory shorebird mapping	Mapping was undertaken in accordance with EPBC Policy Statement 3.21 (DEWHA, 2009b)
Trend analysis	The trend analysis was undertaken by a Senior Research Fellow at RMIT University. The work involved an expert elicitation process involving eight people considered to be experts on the native vegetation of the Cumberland subregion, including representation from academia. As part of this process, several experts reviewed or provided input into the trend analysis method

11 Approach to understanding biodiversity values

This Chapter describes the approach and methods for understanding the biodiversity values and other matters that require assessment within the Plan Area. It includes information about:

- The approach to identifying NSW and Commonwealth matters needing assessment
- The approach to understanding the landscape context
- The surveying and mapping methods for native vegetation communities
- The mapping methods for threatened ecological communities (TECs)
- The surveying and mapping methods for threatened species and their habitats
- The approach to understanding the other matters protected by the EPBC Act

It should be noted that an initial assessment of the implications of the 2019/2020 NSW bushfires on species impacted by the Plan was also undertaken based on available information. This assessment is set out in Part 1 and Supporting Document G.

11.1 IDENTIFICATION OF MATTERS FOR ASSESSMENT

The BAM and ToR require the Assessment Report to identify the NSW and Commonwealth matters that may occur in the Plan Area and that may be impacted by the development.

Section 6.4 of the BAM provides a process to predict all NSW-listed species that may occur in the nominated areas and consider whether any of these species can be excluded from the assessment.

The ToR requires all Commonwealth matters relevant to the Strategic Assessment Area to be identified. Clause 4.2 provides that the level of assessment be proportionate to the level of likely risk of impacts to each matter.

Separate processes were undertaken to identify the NSW and Commonwealth matters needing assessment.

11.1.1 NSW MATTERS NEEDING ASSESSMENT UNDER THE BCAR

PURPOSE

Section 6.4 of the BAM requires several steps be applied to determine the NSW-listed threatened species that require assessment under the BCAR. This process was applied to the nominated areas.

The BAM categorises species into two groups:

- Ecosystem credit species (ECS) – these species can be reasonably predicted to occur at a location based on habitat type and condition
- Species credit species (SCS) – these species cannot be reasonably predicted to occur at a location based on habitat

In some cases, SCS can be both listed as an ECS as well as a SCS, based on species life cycle and breeding requirements.

The process for determining what species require assessment is different for ECS and SCS.

METHOD

NSW-listed species

Relevant NSW-listed species were identified by application of the following three step process:

- Step A: Identification of an initial list of species (Step 1, Section 6.4 of the BAM)
- Step B: Initial exclusion of SCS (Steps 2 and 3, Section 6.4 of the BAM)
- Step C: Consideration of best available ecological data as provided by Section 6.1.1.2 of the BAM

Step A: Identification of an initial list of species (Step 1, Section 6.4 of the BAM)

Identification of an initial list of species using the BAM credit calculator was undertaken in accordance with Step 1, Section 6.4 of the BAM. The calculator uses data contained in the Threatened Biodiversity Data Collection and on Plant Community Types (PCTs) in the nominated areas to predict the initial list of species based on the following:

- Distribution of the species includes the relevant IBRA subregion where the nominated areas occur
- Nominated areas are within any geographic constraints of the distribution of the species in the IBRA subregion
- Species are associated with any of the PCTs identified as occurring within the nominated areas
- Native vegetation cover within the assessment area (including a 1,500 m wide buffer surrounding the boundary of the nominated areas) is equal to or greater than the minimum native vegetation cover required for a species
- Patch size of which the vegetation zone is equal to or greater than minimum value specified for a species

Step A was completed separately for each nominated area. This included inputting PCT data from all PCTs present in the nominated areas (i.e. not just those in the urban capable land) into the BAM calculator (BAM-C). This ensured the widest suite of species were considered from the outset, with some potential candidate SCS later excluded on the basis of a lack of suitable habitat in the urban capable land (further information is provided in Attachment A to Part 3).

All ECS identified in Step A were identified for assessment in the BCAR.

SCS identified in Step A were considered further under Steps B and C.

Step B: Initial exclusion of SCS (Steps 2 and 3, Section 6.4 of the BAM)

Steps 2 and 3 of Section 6.4 of the BAM specify that an SCS may be excluded from needing further assessment because:

- Habitat constraints (as defined in the Threatened Biodiversity Data Collection) confirmed by ground surveys were not present (Section 6.4, Step 2) within a vegetation zone or the nominated areas. The BAM specifies that this step is not applicable where no habitat constraints are listed for a species in the Threatened Biodiversity Data Collection, or
- The species is a vagrant in the IBRA subregion (Section 6.4.1.14), or
- Habitat within a vegetation zone or the nominated areas is substantially degraded (Section 6.4, Step 3). This must be considered based on a field assessment of the habitat constraints or microhabitats of the subject land, or
- An expert report determines that habitat for the species is unlikely to be present (Section 6.4.1.17 (b))

For the most-part, Step B did not result in the exclusion of many SCS from the initial list in Step A as its application at the very large landscape scale of the Plan was not possible. Further, it was not posssible to use an assessment of habitat constraints or degraded habitat to exclude any SCS due to the large size of the assessment area coupled with land access constraints (see Chapter 21). Field assessments were restricted to sites where access was granted by landholders and these limitations meant it was not possible to assess either all vegetation polygons within a vegetation zone, or the entire subject land to adequately determine habitat degradation or the presence / absence of habitat constraints. Furthermore, no species were determined to warrant exclusion on the basis of being a vagrant.

Expert reports were prepared for 14 candidate SCS under Section 6.4.1.21(c) of the BAM, and the majority of the reports concluded that habitat was likely to be present in the nominated areas where the species was identified as a candidate. However four species were excluded from specific nominated areas by the experts.

It was the conclusion of the expert report for *Grevillea juniperina* subsp. *juniperina* within Wilton and GMAC, that the species was unlikely to be growing wild in either nominated area, and has probably never been native to either of these areas (Weston, 2019). The expert also concluded that no suitable habitat for *Pterostylis saxicola* exists in WSA, and it is most unlikely to occur there (Weston, 2018). Similarly the expert report for *Persoonia nutans* concludes that the species is unlikey to occur within the urban capable land in GMAC, or Wilton (Douglas, 2019b). *Melaleuca deanei* was also excluded from occuring within GPEC on the basis of the expert report for that species (Douglas, 2019a).

Step C: Consideration of best available ecological data as prescribed by Section 6.1.1.2 of the BAM

Steps A and B led to a highly conservative list of species needing assessment. However, the accredited assessor considered many of these species unlikely to occur (or that the species habitat was unlikely to occur) within the nominated areas and/or urban capable land based on:

- Knowledge of the species in the subregion
- BioNet records, or
- Peer-reviewed literature

Section 6.1.1.2 of the BAM specifies that:

> *'An assessor may use additional information about a threatened species, in BioNet (e.g. the profile of a threatened species) or published, peer reviewed literature, when assessing the habitat suitability of a site'*

Due to the inability of Step B to be applied comprehensively at the landscape scale of the project, the accredited assessor applied an approach that used Section 6.1.1.2 of the BAM to help provide information and justification for excluding SCS from further assessment. This process was considered necessary to ensure that both:

- The species likely to occur on the subject land were identified, and
- The species unlikely to occur were appropriately excluded

Step C involved a series of workshops with accredited assessors and ecologists from Biosis and Ecoplanning to consider each SCS identified in Step A on the basis of the following (as prescribed by Section 6.1.1.2 of the BAM):

- Best available ecological data
- The Threatened Biodiversity Data Collection
- Species records in BioNet
- Published peer reviewed literature

In relation to species records, it is acknowledged that records do not represent complete information on the absence of a species. However, records do represent the best available information and are suitable to infer trends in distribution and likelihood of occurrence in the landscape. This is particularly the case for the nominated areas which have been extensively surveyed relative to other parts of NSW and it can be reasonably expected that a species would have been previously recorded if present.

The workshops involved:

- Consolidating information on habitat types present within the urban capable land for each nominated area based on field surveys and the most up to date native vegetation mapping
- Reviewing each species habitat preferences based on BioNet and published peer reviewed literature, including habitat constraints identified in the Threatened Biodiversity Data Collection
- Reviewing each species distribution/geographic extent based on BioNet and published peer reviewed literature, including interrogation of records data, including BioNet records
- Application of knowledge and expertise of accredited assessors and ecologists who had surveyed the nominated areas, as well as ecologists with detailed knowledge of the flora and fauna of Cumberland subregion

The exclusion of SCS from the final candidate species list under Step C was based on the factors identified in Table 11-1.

A total of 83 SCS were predicted to occur within the nominated areas. Of these, 41 SCS were determined to be candidate SCS needing further assessment, and 42 were removed.

Table 11-1: Factors for excluding SCS from the final candidate species list under Step C

Factors for excluding SCS	Description
Geographic extent of a species occurring outside one or more of the nominated areas, or urban capable land	This was considered for each species based on: • BioNet records and surveys for this project • BioNet profiles • Final determinations • Conservation advice or recovery plans • Other published peer reviewed literature A total of 28 species were excluded from one or more nominated areas on this basis

Factors for excluding SCS	Description

Lack of suitable habitat within one of more of the nominated areas or urban capable land	This was considered for each species based on:
	• The lack of PCTs associated with the species in the urban capable land
	• An absence of microhabitats associated with:
	  ○ Creeklines/floodplains
	  ○ Sandstone clifflines/outcropping
	  ○ Transitional soil/ecotonal community associations
	  ○ Tree hollows and larger undisturbed vegetation patches suitable for species occurrence and/or breeding
	This was determined based on the accredited assessors knowledge of the nominated areas, and best available ecological data on the species' microhabitat requirements
	A total of 22 species were excluded from one or more nominated areas on this basis

Lack of records in one or more of the nominated areas over the past 55 or more years (up to >200 years)	This was considered for each species based on BioNet records and surveys undertaken for this project. Four flora species were excluded on this basis, these include *Deyeuxia appressa*, *Gyrostemon thesioides*, *Pilularia novae-hollandiae*, and *Thesium australe*. These species are considered locally extinct within the nominated areas. Furthermore, Bush Stone-curlew was also excluded based on being considered locally extinct within the nominated areas. It was concluded that the species no longer occurs in the area because: • Any potential suitable micro-habitats for the species have undergone a long history of degradation and are now considered scarce in urban capable land • There are very few recent records within the subregion • The species has not been recorded in the nominated areas since 1996 (more than a generations length) despite a high level of surveys since that time

NSW-listed TECs

Relevant NSW-listed TECs were identified by:

- Identifying the relationship between PCTs and NSW-listed TECs. In accordance with the BAM, this relationship was identified in the NSW BioNet Vegetation Classification System
- Reviewing updated native vegetation maps that identify the PCTs within the nominated areas
- Conformance with NSW listed TEC profile information (structure, floristics, landscape position, soil association etc.)

RESULTS

The results of the process to identify the matters requiring assessment under the BCAR are presented in Section 11.5 and Attachment A to Part 3. This includes the list of NSW-listed candidate SCS requiring assessment under the BCAR, along with justification for the inclusion or exclusion of species from further assessment.

11.1.2 EPBC ACT MATTERS NEEDING ASSESSMENT UNDER THE SAR

PURPOSE

As required by Section 3.2 of the ToR, the SAR must identify the protected matters that may be impacted directly, indirectly or cumulatively by actions taken under the Plan.

METHOD

This was undertaken by:

- Identifying the full list of protected matters that may potentially be relevant to the Plan and require assessment under the SAR (both within and outside of the Strategic Assessment Area)
- Categorising those matters to identify the subset that have the potential to be impacted and require assessment

A precautionary approach was applied to both steps to ensure that all matters requiring assessment were identified. In accordance with Section 4.8 of the ToR, the approach was supported by peer review of both the method and results.

It is important to note that this process did not relate to how protected matters were assessed. Rather, this step merely identified the matters requiring assessment under the SAR.

Identification of protected matters

The full list of protected matters potentially relevant to the Plan was identified through searches of:

- The Australian Government's online Protected Matters Search Tool
- NSW BioNet
- Atlas of Living Australia
- The Australian Government's Finalised Priority Assessment List (FPAL)

These searches were done using the Strategic Assessment Area boundary plus an additional 10 km buffer. This was considered an appropriate area to identify matters that may be impacted directly, indirectly or cumulatively by the Plan. This work identified the following groups of protected matters as being relevant to the assessment:

- Listed threatened species and ecological communities
- Listed migratory species
- Wetlands of international importance (Ramsar wetlands)
- World and National Heritage
- Commonwealth land

The full list of protected matters was then assigned to one of two categories:

- Category 1: matter needs detailed assessment. These matters are reliant on the Strategic Assessment Area, have some potential to be impacted (directly, indirectly or cumulatively), and are addressed in detail
- Category 2: matter does not need further assessment. These matters are not reliant on the Strategic Assessment Area, are subject to no or very low risk of impacts (directly, indirectly or cumulatively), and are not addressed further

Commonwealth-listed TECs

Commonwealth-listed TECs present in the Strategic Assessment Area that have some potential to be impacted (directly, indirectly or cumulatively), were identified and assigned to Category 1 based on:

- The Australian Government's Protected Matters Search Tool
- Existing native vegetation mapping for the Cumberland Plain (OEH, 2013b, 2016b)
- Detailed native vegetation mapping undertaken within the nominated areas for this project
- Assignment of a PCT in the BioNet Vegetation Classification (formerly known as Vegetation Information System Classification (VIS-C))
- Conformance with Commonwealth-listed TEC profile information (structure, floristics, landscape position, soil association, patch size etc.)

Commonwealth-listed threatened species

Two steps were applied to categorise threatened species for assessment:

- Application of criteria
- Expert review

Application of criteria

Criteria were applied to initially identify the threatened species that may be impacted by actions under the Plan (see Table 11-2). A species was allocated to Category 1 (meaning it required detailed assessment) if it met any of the criteria. Species that did not meet one or more of the criteria were assigned to Category 2 (no further assessment required).

Two senior ecologists with extensive expertise in species within Western Sydney reviewed the criteria and overall approach to ensure that all matters that may be directly, indirectly or cumulatively impacted by the Plan were identified. The ecologists recommended taking a precautionary approach and simplifying some of the criteria.

Table 11-2: Criteria and process for categorising threatened species

Category 1 criteria*	Rationale for the criteria	Process to apply the criteria
1. **The species was identified as a species requiring assessment as part of the BAM process for the nominated areas**	The BAM process identifies the NSW-listed species that may be impacted within the nominated areas. The process is based on a range of detailed on ground surveys and analysis Where these species are also listed as a Commonwealth-listed species they should be assigned to Category 1	See Section 11.5 for a description of the relevant part of the BAM process
2. **The species was subject to a commitment in the Sydney Growth Centres Strategic Assessment Program Report (DECCW, 2010)**	A range of species are subject to commitments associated with the previous Growth Centres strategic assessment. Given the close association in areas that may be affected by the Plan it is appropriate that these species be assigned to Category 1	This criterion was applied through a review of the Growth Centres Program Report to identify relevant species
3. **The Strategic Assessment Area contains a known important population**	Important populations of threatened species require particular consideration under the EPBC Act (DoE, 2013). Where they are present in the Strategic Assessment Area the species should be assigned to Category 1	Important populations within the Strategic Assessment Area were identified through: • Review of recovery plans, conservation advices, species profiles, EPBC policies, and other published literature • Application of the process for mapping important populations in the Strategic Assessment Area It is important to note that any record of an endangered or critically endangered species is considered to form part of an important population (DoE, 2013)
4. **The Strategic Assessment Area contains >5 per cent of all known records in NSW of a species since 1990 on the BioNet Atlas of NSW Wildlife**	Known records provide an indication of the importance of the Strategic Assessment Area to a species. Using a precautionary approach, greater than 5 per cent of records in NSW was chosen as a threshold for assigning species to Category 1	This criterion was applied using post 1990 species records from the BioNet Atlas of NSW Wildlife database. Records within the Strategic Assessment Area were compared to the total number of records across NSW
5. **The Strategic Assessment Area comprises >5 per cent or more of the mapped distribution of the species according to the Department of Agriculture, Water and the Environment's (DAWE) current distribution mapping**	DAWE's distribution mapping of habitat showing where a species is 'known to occur', 'likely to occur' and 'may occur' also provides an indication of the importance of the Strategic Assessment Area to a species. Using a precautionary approach, greater than 5 per cent of a species distribution was chosen as a threshold for assigning species to Category 1	This criterion was applied using distribution statistics provided by DAWE about the percentage of each species distribution within the Strategic Assessment Area

Category 1 criteria*	Rationale for the criteria	Process to apply the criteria
6. It is an FPAL species, and available information suggests it occurs in the Strategic Assessment Area	The FPAL includes species nominated for listing as threatened or for up-listing. Any FPAL species likely to occur in the Strategic Assessment Area warrants assessment and should be assigned to Category 1	Where DAWE's distribution and records information for an FPAL species was available, this was used to determine occurrence in the Strategic Assessment Area Where this information was not available, information from the NSW Threatened Biodiversity Data Collection in BioNet or DAWE's listing documentation was used

* A species was allocated to Category 1 if it met any of the criteria

Review of the initial list

The initial list was reviewed by two expert senior ecologists to confirm the categorisation or to move species between categories based on specific expert knowledge. This step was important as it provided the opportunity to consider specific information to ensure that all species that may be impacted were identified.

The findings of this review are incorporated into the results in Chapter 28.

Migratory species

Migratory species were addressed in three groups:

- Migratory shorebirds
- Migratory birds addressed in the *Draft referral guideline for 14 birds listed as migratory species under the EPBC Act* (DoE, 2015)
- Other migratory species

Migratory shorebirds

Thirty-seven migratory shorebirds visit Australia each year. They are addressed as a group in EPBC Act Policy Statement 3.21 (DoE, 2017). Given the overlap in habitat used by many of these species and the similar way they are treated under the EPBC Act, any migratory shorebirds that were known to occur in the Strategic Assessment Area were assigned to Category 1. This was based on post 1990 records within the area from NSW BioNet and Birdlife Australia.

Any species without records were assigned to Category 2.

Other migratory birds

Fourteen migratory bird species are addressed in the EPBC guideline (DoE, 2015) for which a similar approach to shorebirds was applied. Any species with records in the Strategic Assessment Area was assigned to Category 1.

Any species without records were assigned to Category 2.

Remaining migratory species

For the remaining migratory species, two steps were applied to categorise them:

1. **Application of criteria:** Criteria were applied to initially identify the other migratory species that may be impacted by actions under the Plan (see Table 11-3). A species was allocated to Category 1 if it met any of the criteria. Species that did not meet one or more of the criteria were assigned to Category 2
2. **Expert review:** The list was reviewed by two senior ecologists to confirm the categorisation or to move species between categories based on specific expert knowledge

Table 11-3: Criteria and process for categorising the remaining migratory species

Category 1 criteria*	Rationale for the criteria	Process to apply the criteria
1. **The Strategic Assessment Area supports important habitat or an ecologically significant proportion of a species**	"Important habitat" and "ecologically significant proportion" are key concepts for migratory species (DoE, 2013). Where these are present within the Strategic Assessment Area it is appropriate to assign a species to Category 1	Important habitat and ecologically significant proportion need to be determined on a species-by-species basis. The guidance around these concepts from the EPBC Act significant guidelines (DoE, 2013) were applied Information from recovery plans, conservation advices, species profiles, EPBC policies, and other published literature were used to identify if the Strategic Assessment Area supported important habitat or an ecologically significant proportion of a species
2. **The Strategic Assessment Area contains >5 per cent of all known records in NSW of a species since 1990 on the BioNet Atlas of NSW Wildlife**	Known records provide an indication of the importance of the Strategic Assessment Area to a species. Using a precautionary approach, greater than 5 per cent of records in NSW was chosen as a threshold for assigning species to Category 1	This criterion was applied using post-1990 species records from the BioNet Atlas of NSW Wildlife database. Records within the Strategic Assessment Area were compared to the total number of records across NSW

* A species was allocated to Category 1 if it met any of the criteria

Wetlands of international importance (Ramsar)

There are no Ramsar Wetlands within the Plan Area. However, Towra Point Nature Reserve occurs downstream of the Plan Area and was assigned to Category 1.

World and national heritage

Any World or National Heritage places within or within the vicinity of the Plan Area were assigned to Category 1.

Commonwealth land

Any Commonwealth land within the Plan Area was assigned to Category 1.

Finalised Priority Assessment List (FPAL) matters

Any matters on FPAL that were known to occur in the Strategic Assessment Area were put into Category 1.

RESULTS

The results of the process to identify the matters requiring assessment under the SAR are presented in Chapter 28.

11.2 LANDSCAPE CONTEXT

11.2.1 LANDSCAPE CONTEXT WITHIN THE NOMINATED AREAS

PURPOSE

Section 4 of the BAM requires the BCAR to describe:

- Landscape context, including landscape features such as waterways, wetlands and habitat connectivity
- Site context, including native vegetation cover and patch size

METHOD

Native vegetation cover

Native vegetation cover was assessed within a 1,500 m buffer from the urban capable land footprint of each of the nominated areas separately, and entered into the BAM Calculator.

This approach was undertaken in accordance with Section 6.4.1.3 of the BAM and to ensure that all ECS and SCS with a native vegetation cover class requirement lower than, or equal to that of each nominated area, were considered. This ensured accurate and area specific information was used, and that no species were excluded based on a higher overall value for native vegetation cover resulting from averaging across all nominated areas.

Rivers and streams

Rivers and streams were identified in accordance with Appendix 3 of the BAM.

Wetlands

Wetlands were identified through aerial photographic interpretation (API), as well as data in the Digital Topographic Database hydro area layer (LPI, 2016) and the Directory of Important Wetlands (DoEE, 2018).

Habitat connectivity

Habitat connectivity refers to the degree of connectedness of areas of habitat. Habitat connectivity can include:

- Corridors of vegetation linking other areas of habitat
- Isolated patches of habitat that provide 'stepping stones' between other areas of habitat
- Habitat features (such as large trees with hollows) scattered within areas of non-habitat (e.g. urban land) that provide habtiat connectivity between intact areas of habitat

Habitat connectivity within the nominated areas was mapped by:

- Identifying Biodiversity Investment Opportunities Map (BIO Map) regional corridors and core areas (OEH, 2015). The BIO Map project aims to achieve better biodiversity outcomes by directing investment funding to the strategic locations of greatest benefit. BIO Map corridors/core areas are likely to be the most important areas of habitat connectivity in the nominated areas for most species. EES had only identified BIO Map corridors within the boundaries of the Cumberland subregion. To undertake the mapping for the small parts of the nominated areas outside the Cumberland subregion the Priority Conservation Lands layer (DECCW, 2010) (EES used this layer as basis for BIO Map) or the native vegetation map (see Chapter 19) was used to extend the BIO Map corridor mapping
- Identifying local corridors using the native vegetation mapping to identify connected patches of native vegetation. This was done visually in GIS, with only contiguous patches identified as being connected
- Identify any remaining native vegetation not within a regional corridor or local corridor as:
    - Connected – within 100 m of another patch of woody vegetation
    - Isolated – greater than 100 m from another patch of woody vegetation

Key areas of habitat connectivity in the nominated areas are shown in Chapter 24.

Areas of geological significance and soil hazard features

The likely locations of areas of geological significance, including cliffs, caves and escarpments, were identified on the basis of existing knowledge of senior ecologists, field investigation results, topographic and geological maps, and the following datasets:

- Geological sites of NSW (Cartoscope, 2019)
- Karst Environments of NSW (OEH, 2018c)

Soil hazard features including dryland salinity, acidification, compaction, structural breakdown, sodicity and contamination were identified on the basis of the following datasets:

- NSW soils datasets at 1:100,000 from the EES data portal
- NSW geology datasets at 1:250,000 from the Department data portal
- eSpade (OEH, 2018b)
- NSW (Mitchell) Landscapes (OEH, 2018d)
- Western Sydney Hydrogeological Landscapes (OEH, 2011)

RESULTS

The results of the landscape context analysis within the nominated areas are provided in Chapter 18.

11.2.2 LANDSCAPE CONTEXT WITHIN THE STRATEGIC ASSESSMENT AREA

PURPOSE

Clause 3 of the ToR requires the SAR to describe the nature of the environment within the Strategic Assessment Area, and other areas outside this area that may be impacted by actions taken under the Plan. This includes:

- A description of historical and current land use
- The extent and quality of native vegetation
- The nature of the environment (including ecosystem processes and threatening processes)
- A description of landscape context for key matters (including habitat connectivity, fragmentation, ecological processes)
- Consideration of environmental variation
- A map of areas that are already protected

METHOD

The nature of the environment was described through a review of relevant literature. Key source documents are referenced in Chapter 28 and included:

- The Cumberland Plain Recovery Plan (DECCW, 2011)
- Cumberland subregion BIO Map report (OEH, 2015)
- A range of technical papers on the ecology and ecological processes of the Cumberland subregion
- Relevant government policies and guidelines

Habitat connectivity within the Plan area was mapped as per the method described above for the nominated areas. Key areas of habitat connectivity in the Plan area are shown in Chapter 28.

RESULTS

The results of the landscape context analysis within the Strategic Assessment Area are provided in Chapter 28.

11.3 NATIVE VEGETATION

11.3.1 OVERALL APPROACH TO NATIVE VEGETATION MAPPING

Native vegetation maps were prepared:

- Within the nominated areas to meet the requirements of the BAM. Detailed mapping of the nominated areas was undertaken based on a combination of field surveys and API (OEH, 2013b, 2016b)
- Within the Strategic Assessment Area outside the nominated areas to meet the requirements of the ToR. Mapping of the Strategic Assessment Area was based on existing native vegetation maps

11.3.2 NATIVE VEGETATION MAPPING WITHIN THE NOMINATED AREAS

PURPOSE

Section 5 of the BAM requires the BCAR to identify and map for the nominated areas:

- Extent of native and exotic vegetation
- PCTs and TECs
- Vegetation integrity

METHOD

The native vegetation mapping in the nominated areas was undertaken:

- After reviewing existing native vegetation mapping and data gaps, with new vegetation mapping undertaken over the entire nominated areas rather than relying on existing native vegetation mapping
- Using a systematic field-based floristic vegetation survey, capturing plot based data in accordance with the BAM, with results then fed back to GIS/ecologists developing or updating the native vegetation map

Where land access was available, plot-based floristic vegetation survey was completed in a stratified manner ensuring all vegetation zones were sampled across the nominated areas and in consideration of environmental variation.

Where access was unavailable:

- Existing vegetation mapping was used in conjunction with other existing, and project derived desktop-based data to accurately map vegetation within the nominated areas
- Rapid assessment ground-truthing was undertaken if suitable vantage points in public areas allowed. At these vantage points ecologists confirmed continuity of vegetation communities and assessed broad condition state and level of habitat degradation to verify the project's vegetation mapping wherever possible

The methods used to develop the vegetation map are further described below.

Draft PCT map based on desktop analysis

A draft PCT map for each nominated area was prepared based on desktop analysis. This involved:

Step 1: Collating relevant datasets and GIS layers, including:

- Recent Nearmap imagery at 15 cm resolution
- NSW landuse polygons (OEH, 2013a)
- NSW soils datasets at 1:100,000 from the NSW Government data portal
- NSW geology datasets at 1:250,000 from the NSW Government data portal

Step 2: Processing multispectral aerial imagery into Normalised Difference Vegetation Index (NDVI) imagery

Step 3: Amalgamating previous native vegetation mapping across the nominated areas

Step 4: Combining two existing EES maps of native vegetation within the Cumberland subregion (OEH, 2013b, 2016b) into a single layer and clipping the layer to the nominated area boundaries

Step 5: Creating a canopy height model using 1 m LiDAR data (see Section 13.2 for details on the LiDAR data used)

Step 6: Processing the canopy height model into amalgamated canopy polygons for vegetation over 1 m in height (exotic vegetation only)

Step 7: Manually creating and attributing GIS polygons to accurately capture native vegetation extent, type and condition

Step 8: Compiling the data into a single GIS map for the nominated areas with 500 m by 500 m grid squares

Interpretation of Nearmap imagery, desktop analysis and refinement of existing native vegetation mapping (OEH, 2013b, 2016b) using the BioNet Vegetation Classification database (OEH, 2018a) and the ArcGIS mapping application was undertaken by botanists experienced in the survey and identification of the PCTs of the subregion. The botanists moved cell by cell through the grid within each nominated area. All vegetation polygons were created with reference to the existing native vegetation mapping and any unmapped vegetation was assessed and assigned a PCT.

Native vegetation community extent

Native vegetation community extent within the nominated areas was determined using API, existing vegetation mapping (OEH, 2013b, 2016b) and GIS analysis. All native vegetation, including native ground cover and the canopy area of trees was mapped. A rule-set was applied to ensure mapping of vegetation extent was consistent and precautionary across the mapping area. The rule-sets included:

- Map vegetation to canopy extent with a +/-2m buffer where grassland surrounds the mapped polygon
- Consider visible changes in condition and obvious changes to vegetation type (PCTs)
- Include gaps within surrounding polygons where:
    - Gaps are ≤60m wide and surrounded by intact vegetation, except where significant disturbance is evident
    - Gaps are ≤30m wide and surrounded by thinned vegetation (or partly surrounded by thinned and partly by intact), except where significant disturbance is evident
- Map scattered trees comprising mature gum trees as a single polygon where trees occur ≤60m apart and the internal area is +/- uniform grassland
- Map scattered trees comprising shrubs or scattered regrowth as separate polygons where separated by ≥10m
- Map a 30m buffer along the edges of intact and/or thinned vegetation in grassland areas that appear to have lower levels of disturbance history (i.e. these areas may comprise derived native grassland)
- Excise roads and waterbodies, but map canopy overhanging
- Map aquatic vegetation where it is contiguous with vegetation on the adjacent bank

The extent of native vegetation within the nominated areas was mapped by Biosis botanists using purpose-built GIS web apps supporting hi-definition aerial imagery, over multiple capture dates and seasons. This was done to ensure accuracy of tree canopies versus shadows, extents of more disturbed shrubby areas, and extents of dynamic wetland / swampy areas. A grid-based approach was used whereby Biosis mapping staff would systematically move through the nominated areas drawing vegetation extent polygons to accurately capture areas of vegetation, and then subsequently attribute (and/or cut) polygons with vegetation type (PCT) and condition data.

Existing vegetation mapping (OEH, 2013b, 2016b) was used as a guide, but was not relied upon to determine native vegetation cover and extant. LiDAR derived datasets including a canopy height model and digital elevation model, as well as slope and ruggedness models were also used to differentiate types of vegetation.

Native grasslands were challenging to map in areas where ground validated data could not be captured due to access restrictions. However, ground validated data on the presence of native and exotic grasslands were used as reference point by Biosis mapping staff to help determine the status of areas that lacked field data.

The final process to map areas of native grasslands (i.e. derived native grasslands) involved undertaking detailed investigation of high resolution aerial imagery, over multiple capture dates and seasons, to ascertain areas of significant ground disturbance, paddock scale historical and ongoing management practices, areas of heavy grazing and/or compaction, or discernible areas of exotic pasture, which were then ruled out from being potential native grasslands. The NSW 2017 Landuse mapping dataset was also interrogated to ascertain areas considered unlikely to support native grasslands, which included areas mapped as supporting the following land uses:

- Areas observed (or assumed) to be recently cleared under rural allowable activities
- Cropping
- Exotic areas >90% areas identified as vulnerable regulated land in relation to slope
- Grazing irrigated modified pasture
- Grazing modified pastures
- Grazing native vegetation (partly associated)
- Intensive animal production
- Irrigated perennial horticulture
- Manufacturing and industrial
- Mining
- Reservoir/dam
- Residential and farm infrastructure

- Services

Following the determination of areas of significant disturbance that do not conform to native grasslands, and any areas of exotic grasslands, the remaining grassland areas were either mapped as native vegetation (derived native grassland) or native grassland 'to be confirmed', where some doubt remained. Following the completion of the field campaign all areas of native grassland 'to be confirmed' that remained were attributed as native grassland vegetation.

To further refine the mapping of native versus exotic grasslands, multispectral imagery analysis was attempted using NDVI imagery. However, the initial results of this method did not appear to provide reliable classification of native/exotic grassland extent and this methodology was not used in the creation of the vegetation map.

Identification of Plant Community Types

All PCTs potentially present within the nominated areas were determined using the BioNet PCT identification tool and the Tozer-types PCT identification tool, as well interrogation of BioNet data and existing vegetation mapping projects (OEH, 2013b, 2016b) for vegetation communities of the Cumberland subregion.

Botanists experienced in the survey and identification of the PCTs of the Cumberland subregion attributed updated vegetation polygons that accurately represented vegetation extent with the appropriate PCTs based on consideration of landscape and location specific factors. Existing vegetation mapping was used as a basis for PCT attribution. The accuracy of the mapping was assessed and the 'best fit' PCT for each vegetation polygon was determined through:

- API of high resolution Nearmap (over multiple capture dates and seasons)
- Consideration of landform and landscape positioning
- Consideration of soil and geology mapping
- LiDAR derived datasets including canopy height model, digital elevation model and slope and ruggedness model
- All available field data including both project captured and BioNet floristic data, as well as the use of Google Street Viewer where appropriate, all with reference to BioNet data PCT descriptions and vegetation mapping PCT profiles (OEH, 2013b, 2016b; Tozer, Turner et al., 2010)

LiDAR derived datasets provided a useful tool to distinguish between PCTs, for example PCT 849 and PCT 850. The digital elevation model and slope models could be used to discern higher/steeper areas more suited to PCT 850 that were less discernible using other datasets. The canopy height model was useful in determining the presence of remnant canopy trees, or large paddock trees, and discerning these from planted trees.

All data collected in the field was analysed to determine the most suitable PCT based on floristics with all data captured being fed back to GIS mapping staff to update the native vegetation map based on ground validated data. This included rapid assessment ground-truthing surveys undertaken at the request of botanists preparing the native vegetation maps (where ground validation could provide clarity about areas of uncertainty associated with the desktop analysis).

In making use of all available desktop and field validated data the process used to map PCTs is considered appropriate for the very large scale of the project, where land access constraints prevented ground validation of much of the nominated areas. All PCTs potentially present within the nominated areas, including PCT 774, PCT 781, PCT 877 and PCT 1800 (representative of TECs with little known distributions, small or restricted spatial extents, dynamic wetter boundaries, or potentially difficult to detect using aerial imagery), were specifically considered in developing the native vegetation map, and three of these four PCTs were mapped across the subject land in the final PCT map.

It is acknowledged that there is a slight risk that these four PCTs/TECs have been under-mapped. However, the systematic and methodical approach undertaken to develop the native vegetation map, by experienced botanists, along with the ongoing reference to all best available data (including field data whenever available) is considered to sufficiently mitigate the risk of small areas not being mapped, and the even smaller risk of any small under-mapped areas occurring within urban capable land. This is considered to be the case for PCT 774, as urban capable land is not proposed in the landscape position known to support this PCT, and the PCT was not recorded during any ground validation surveys. The methodology used is appropriate for the scale of the project.

Polygons with a lower level of confidence, based on a paucity of data, or fewer distinguishing attributes suitable for splitting similar PCTs, occur in the vegetation dataset and have been attributed with a low level of confidence. Despite this, the overall confidence in the native vegetation mapping in the context of the very large scale of the project is high.

Determination of vegetation condition

A condition type for each vegetation polygon was assigned through analysis of canopy structure using LiDAR, the canopy height model, air photo interpretation of the Nearmap imagery, and the use of Google Street Viewer where appropriate. In most instances, subject to land access restrictions, this was verified in the field by collection of data in accordance with the BAM. The condition states used for each vegetation polygon were:

- **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present. This condition state was assigned during the desktop mapping to areas where the Nearmap imagery indicated significant patches of continuous canopy and the canopy height model indicated vegetation in both the upper and middle storeys
- **Thinned:** This condition state was assigned to native vegetation in various states of modification, including:
    - Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT
    - Wooded vegetation that has been under scrubbed. This condition state was assigned during desktop mapping to areas where the Nearmap imagery indicated patches of notably reduced canopy density, which was typically where the canopy height model indicated canopy and visible ground only, with no discernible shrub layer or structural complexity
- **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed. This condition state was assigned during the desktop mapping to areas where the Nearmap imagery and LiDAR canopy polygons indicated one or a few likely native trees surrounded by cleared land
- **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands. Areas of potential derived native grassland (DNG) were identified from the Nearmap imagery and later verified or reclassified in the field. Grasslands were considered to be DNG where they had a vegetation integrity score of greater than or equal to 15 (based on data collected in the field). Where grasslands were dominated by exotic species and the vegetation integrity score was less than 15, these were considered to be 'non-offsettable grasslands' (NOG)
- **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species. This condition type was also used to map areas of exotic vegetation

In determining vegetation condition in accordance with these definitions for each vegetation polygon, a rule-set was considered to ensure this work was consistent and precautionary across the mapping area. This included:

- Using all available data sources when considering PCTs; existing mapping, soils layer, geology layer, LiDAR derived layers, watercourses, slope/topography, aspect, mapping profiles, etc
- Assigning vegetation to the intact condition category where there was any uncertainty about whether a polygon in thinned condition could be in the higher condition category
- Consideration of the expected density of tree and shrub layers for each PCT when assigning condition and considering evidence for disturbance. For example, PCT 849 in intact condition may regularly have gaps in vegetation layers whereas this is less likely for PCT 1395
- Including confidence level fields in the data and providing regular feedback to botanists about low confidence areas that would benefit from field verification

Final draft PCT maps

Draft PCT maps were made available online to the ecologists in the field to allow an ongoing process of field verification and refinement. Ecologists undertook rapid assessment ground-truthing and amended the PCTs and/or condition states assigned during the desktop analysis. Amendments were recorded in the field using Collector for ArcGIS and later cross checked with field data.

Final draft maps were used to determine the number of plot-based survey sites required to be surveyed to meet BAM requirements. As plots were surveyed, the number of plots required for each PCT and condition state (in Section 5.3.4 of the BAM) was reviewed and the vegetation mapping was updated to develop a final PCT map for each nominated area.

BAM plot data was analysed to update the vegetation map. BAM plot floristics were assessed to determine whether the correct PCT and vegetation condition had been attributed during the desktop mapping process.

This process involved analysis of the floristic composition using both the BioNet (PCT ID tools) as well as 'Tozer tool' spreadsheets to determine to the 95% confidence interval (where sufficient data was available) for the 'best fit' PCT based on the profile data provided in Tozer and Turner et al. (2010).

Condition was tested by analysing the floristic structure and composition of each plot, and comparing it to what would be considered to be an 'Intact', 'Thinned', 'Scattered Trees' condition example of the determined PCT. BAM VI scores were not used to attribute vegetation condition, this was done through analysis of the raw floristic data.

Floristic plot surveys

A stratified field survey was designed to verify and identify PCTs within the nominated areas, including:

- PCT and condition state
- Environmental variation
- Gaps in existing mapping and site data

Plot surveys were undertaken in accordance with the requirements of the BAM by accredited assessors and ecologists considering environmental variation and in a stratified manner, where land access was permitted allowed.

The number of plots surveyed for each PCT and vegetation zone within the nominated areas are shown in Table 11-5.

Plot surveys were undertaken during the period February 2018 to March 2019 with an additional few plots undertaken in October 2021 (due to development footprint changes through the life of project). Where land access was unavailable, existing vegetation mapping was used in conjunction with available desk-based data and rapid assessment ground-truthing to verify or alter existing vegetation mapping.

Plot data was collected from a 20 m x 20 m plot to capture:

- Species presence (by scientific name and any relevant common name)
- Stratum and layer in which each species occurs
- Growth form of each species (as per the BAM)
- Percent foliage cover
- Abundance count (as per the BAM)

The PCT at each plot location was assigned in the field and later verified by assessing several attributes including soil type, landscape position, diagnostic species and community structure. Floristic data collected from the plot surveys was analysed to identify PCT to the best match using the BioNet PCT identification tool.

The PCT results obtained from the identification tool were then checked by a senior ecologist for any discrepancies and a final PCT was allocated to the plot and to the broader vegetation community polygon.

The vegetation maps were continually updated throughout this process.

Plot data collected during previous surveys in accordance with the previous BioBanking Assessment Method (BBAM) was also used to supplement plot data collected in accordance with the BAM. Additional data was collected to supplement the BBAM data in order to meet BAM requirements, including:

- Tree stem count
- 1 x 1 metre plots (litter, bare ground, cryptogram and rock cover)
- High threat weed cover
- Updated growth forms

Vegetation integrity assessment

Vegetation zones

Areas of each PCT in different broad condition states were stratified into separate vegetation zones. Derived grasslands were assessed against the benchmark data for the original, or likely original PCT, and included as a separate vegetation

zone. Non-offsettable Grasslands were also included as a separate vegetation zone. A map of vegetation zones was prepared by GIS consultants using the final native vegetation map.

To ensure consistency of data across the assessment area and to prevent over-complicating the assessment approach and data collection requirements, vegetation zones were not broken down by nominated area. For example, vegetation zone 849 (thinned) occurs across all four nominated areas, and all data collected from within that zone has been pooled to determine the vegetation integrity score, independent of where each plot was collected.

This approach ensured that an accurate and consistent landscape scale vegetation integrity assessment for each vegetation zone was undertaken, which is considered the most suitable approach for an assessment of this scale.

Patch size

The patch size of each vegetation zone was assigned using GIS based on the final native vegetation map as follows:

- Vegetation zones were assigned to the same patch where they were located within 100 m of each other for intact native woody vegetation and within 30 m of each other for intact native non-woody vegetation
- Any intact native vegetation that adjoined vegetation zones beyond the nominated areas was included
- Each patch was digitised, and separate polygons were mapped where multiple patches existed
- The area of each patch in hectares was calculated

Site condition

For each vegetation zone identified within the urban capable land or major transport corridors, a quantitative measure of composition, structure and function was determined through plot and transect surveys in accordance with the BAM.

Table 11-4 shows the attribute data collected.

Table 11-4: Site condition attributes

Growth form groups to assess composition and structure	Attributes to assess function
Tree	Number of large trees
Shrub	Tree regeneration
Grass and grass like	Tree stem size class
Forb	Total length of fallen logs
Fern	Litter cover
Other	High threat exotic vegetation cover
	Hollow-bearing trees

Vegetation integrity plot surveys

For this Assessment Report, the plots used for floristic survey were also used to assess vegetation integrity. Plots and transects were established to provide a representative assessment of the vegetation integrity of the vegetation zone. Plots were undertaken on properties where land access was available, which resulted in a number of plots being collected in patches of vegetation outside the urban capable land or major transport corridors of the nominated areas. All plots were collected within vegetation contiguous with the urban capable land or major transport corridors within the nominated areas, and within vegetation mapped specifically for this assessment.

Plots were randomly located within each vegetation patch using the following method:

- PCT vegetation polygons identified based on the desktop native vegetation mapping were verified in the field to confirm or revise PCT and/or extent
- Locations of BAM plots were determined with the aim of capturing the representative condition of the PCT within the zone, avoiding bias wherever possible
- Ecotones, vehicle tracks and their edges, or other disturbed areas that are readily distinguishable from the broad condition state of the vegetation zone were avoided

- In large patches, the orientation of transects were randomly assigned by throwing an object flagged with tape into the patch of vegetation, the direction that the tape pointed following landing was assigned the plot orientation
- In smaller patches of vegetation, particularly narrow, linear strips, the location of plots was determined based on capturing a representative sample of the patch, avoiding edge areas where possible

The floristic survey plots were 10 m either side of the first 20 m of the transect line (nested within the larger 0.1 ha quadrat).

The following data were collected from the plots and transects:

- 20 m x 20 m plot: floristic data (composition and structure) attributes listed in Table 11-4
- 20 m x 50 m plot: function attributes listed in Table 11-4 (except litter cover)
- Five 1 m x 1m sub-plots: average litter cover

A minimum of 131 plots are required for the assessment, with 251 plots completed across the 31 vegetation zones assessed. Table 11-5 shows the number of plots/transects required to be surveyed to meet BAM requirements for each vegetation zone, and the number of plots and/transects completed for this Assessment Report.

Plot data was supplemented in some cases with data collected previously for other projects in accordance with the Biobanking Assessment Methodology (BBAM). This was done by using BBAM floristic plot data and collecting BAM function attribute data at the locations of previous BBAM plots to supplement this floristic data.

This was largely only used to add to the number of plots collected across the nominated areas rather than to meet minimum plot requirements under BAM. A total of 53 BBAM plots collected across Wilton were upgraded to BAM plots and used to supplement data for PCTs 849 and 1395 across all vegetation zones. However, all of these vegetation zones, with the exception of PCT 1395 Scattered Trees and PCT 1395 Non-offsettable Grassland, would meet the minimum required number of plots under BAM without the use of these additional BBAM plots.

Of the 5 plots collected within PCT 1395 Scattered Trees, 3 were upgraded BBAM plots, with the minimum number of plots required being 4. Of the 9 plots collected within PCT 1395 Non-offsettable Grassland, 3 were upgraded BBAM plots, with the minimum number of plots required for impacts being 7.

Attachment D provides additional detail about the number and location of BAM plots collected during field work, including a breakdown of plots by nominated area and land category (urban capable land, major transport corridors, or non-certified land outside the development footprints). Information is also provided on PCT and vegetation zones, what plots were used to calculate vegetation integrity, and what plots were supplemented by use of BBAM data.

Table 11-5: Number of plots surveyed for each PCT and vegetation zone within the nominated areas

PCT	State	Total impact area (ha)	Minimum plots required	Total plots completed
724	Intact	7.2	3	4
	Thinned	75.3	5	5
	Scattered Trees	25.7	4	4
725	Intact	16.0	3	3
	Thinned	18.7	3	7
	Scattered Trees	2.9	2	2
781	Thinned	4.2	2	4
830	Intact	0.04	1	1
	Thinned	0.01	1	2
835	Intact	13.9	3	3
	Thinned	150.0	6	6
	Scattered Trees	22.1	4	6

PCT	State	Total impact area (ha)	Minimum plots required	Total plots completed
	Non-offsettable Grassland	1201.3	8	8
849	Intact	27.5	4	9
	Thinned	301.7	7	18
	Scattered Trees	120.6	6	12
	DNG	227.4	6	16
	Non-offsettable Grassland	5343.1	8	18
850	Intact	4.0	2	9
	Thinned	43.63	4	6
	Scattered Trees	11.52	3	4
	DNG	195.15	6	6
	Non-offsettable Grassland	704.9	7	9
1395	Intact	45.7	4	16
	Thinned	145.6	6	30
	Scattered Trees	41.0	4	5
	DNG	227.49	6	15
	Non-offsettable Grassland	793.5	7	9
1800	Intact	0.7	1	4
	Thinned	24.0	4	8
	Scattered Trees	1.55	1	2
		Total	**131**	**251**

Final PCT map and updates to native vegetation mapping following public consultation

Following completion of field work the native vegetation map was finalised in consideration of all floristic data collected in the field and prior to public submission of the draft Assessment Report.

Native vegetation map was then updated following public consultation. The mapping was updated where landholders provided evidence in submissions as part of the public consultation process to support changes to the mapped vegetation on their properties. The process for updating mapping involved:

- Reviewing submissions and undertaking further analysis of the evidence provided in the submission(s) and the data used by the consulting team to create the mapping where changes to mapping had been requested
- Where sites were not visited on ground by the project team and clear evidence was provided by a BAM Accredited Assessor in the submission, these changes were accepted and the mapping was updated

There were circumstances where the geometry of vegetation mapping (polygons) provided via public submissions and based on field-validated mapping were different. In these circumstances, the geometry of the field-validated mapping was accepted and the mapping updated if prepared by a BAM Accredited Assessor.

Where there was a challenge to the mapping that had been based on field-validated data, a comparison of the data collected by the consulting team was undertaken where the data provided in the submission was field-validated by a BAM Accredited Assessor. The data considered best fit was applied, and the mapping updated where necessary.

RESULTS

The native vegetation maps of the nominated areas, including plot locations relative to vegetation zones, are provided in Chapter 19.

11.3.3 NATIVE VEGETATION MAPPING ACROSS THE BROADER STRATEGIC ASSESSMENT AREA

PURPOSE

Clause 3 of the ToR requires the SAR to describe the nature of the environment within the Strategic Assessment Area. This includes the extent and quality of native vegetation.

METHOD

The approach to identify and map native vegetation across the broader Strategic Assessment Area involved the following steps.

Step 1: Collating the most recent and highest resolution existing native vegetation mapping data relevant to the Cumberland subregion. This data included:

- Native Vegetation of the Sydney Metropolitan Area Version 3.0 (OEH, 2016b)
- Remnant Vegetation of the Western Cumberland subregion, 2013 Update (OEH, 2013b)
- Native Vegetation of Southeast NSW (Tozer, Turner et al., 2010)
- Biometric Vegetation Compilation for the South East Local Land Services Region (Eco Logical Australia, 2015)

Step 2: Merging the data into a single native vegetation data layer for the Cumberland subregion using GIS and clipping the data to the Cumberland subregion boundary

Step 3: Incorporating the updated the native vegetation maps for the nominated areas into the single native vegetation data layer for the parts of the Cumberland subregion within the nominated areas

Step 4: Reviewing vegetation condition or disturbance data held within the attributes the existing mapping data (Step 1) and updating this data to align with the condition types used for the nominated areas (see Section 11.3.2)

Step 5: Where condition data was unavailable in the existing mapping data, undertaking a desktop assessment of the vegetation polygons and determining condition based on patch size, connectivity and edge impacts. This was only required for the Tozer et al (2010) and Eco Logical Australia (2015) data layers

RESULTS

The native vegetation maps of the nominated areas are provided in Chapter 19.

11.4 THREATENED ECOLOGICAL COMMUNITIES

11.4.1 OVERALL APPROACH TO TEC MAPPING

To meet the requirements of the BAM and the ToR, TEC maps have been prepared for all:

- NSW-listed TECs (see Section 11.1.1) within the nominated areas
- Commonwealth-listed Category 1 TECs (see Section 11.1.2) within the Strategic Assessment Area

TECs were mapped based on associations between PCTs and TECs and rule-sets applied to these associations to refine the maps based on TEC definitions. Separate rule-sets were applied to NSW-listed TECs and Commonwealth-listed Category 1 TECs because of the typically different definitions of each TEC under the BC Act and EPBC Act.

Table 11-6 summarises the mapping approaches within and outside the nominated areas for NSW-listed TECs and Commonwealth-listed Category 1 TECs.

Table 11-6: Summary of mapping approaches for NSW- and Commonwealth-listed TECs

TECs	Mapping area	Mapping method
NSW-listed TECs	Nominated areas	Simple rule set specific to NSW-listed TECs applied to updated native vegetation maps of the nominated areas (see Section 11.3). The rule set applied PCT associations to map NSW-listed TECs and in some cases addressed the condition of the TEC by removing areas of non-offsettable grasslands from the TEC (see Table 11-7)
Commonwealth-listed Category 1 TECs	Strategic Assessment Area	Rule set specific to Commonwealth-listed TECs applied to: • Within the nominated areas – updated native vegetation maps of the nominated areas (see Section 11.3) • Outside the nominated areas – existing native vegetation maps of the Cumberland subregion (see Section 11.3)

11.4.2 NSW-LISTED TECS

PURPOSE

Section 5 of the BAM requires the BCAR to:

- Identify any TECs that are associated with PCTs, or the most likely PCT
- Map the extent of TECs

METHOD

The method to identify and map NSW-listed TECs within the nominated areas was based on the following steps.

Step 1: The updated native vegetation map (see Section 11.3) was used to identify areas of potential TECs on the basis of associations between PCTs and TECs and the rule set in Table 11-7

Step 2: A draft map showing candidate TECs was created by GIS consultants on the basis of Step 1

Step 3: Plots were surveyed in the field within and outside potential TEC areas. The plot data were cross checked by ecologists with the definition of TECs using the BioNet PCT identification tool and against final determinations by the NSW Scientific Committee, to confirm that the specific criteria as shown in Table 11-7 were met for the TEC at that location. Where no field survey of a potential TEC was possible, the TEC was assumed to be present at that location

Step 4: Draft TEC maps for the nominated areas were developed and a report on the method and field verification was prepared for consultation and review by regulators

Step 5: The method and rule set were amended based on feedback from regulators. Final TEC maps for the nominated areas were prepared based on the updated method and rule-set and final native vegetation maps. Table 11-7 shows the rule set developed for mapping NSW TECs

GRASSLAND TECS

Where derived native grasslands form part of a TEC listing all such vegetation zones were mapped as the relevant TECs. Where grasslands were assessed as potentially supporting a native component, but were not determined as derived native grasslands, they were not considered to form part of the relevant TEC. These vegetation zones were deemed 'non-offsettable grasslands' and floristic plot data was collected in accordance with the BAM to determine the associated vegetation integrity score. In each case, the vegetation integrity score was found to be less than 15, which is lower than the minimum score required to offset a TEC in accordance with the BAM (Section 10.3). Non-offsettable grasslands with a vegetation integrity score of less than 15 were not considered to form part of a TEC as the vegetation is considered so degraded it no longer meets the minimum requirements for the TEC or requires any offsetting.

Table 11-7: Rule set for mapping NSW listed TECs within the nominated areas

PCT	NSW TEC	Condition state	Specific criteria – field verification
724 Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	*Shale Gravel Transition Forest in the Sydney Basin Bioregion*	All	Species composition, elevation, soils and landscape position met based on final determinations of the NSW Scientific Committee
725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	*Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	All	
781 Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	*Freshwater wetlands on coastal floodplains of the NSW North Coast, Sydney Basin and South East Corner bioregions*	All	
830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*Moist Shale Woodland in the Sydney Basin Bioregion*	All	
835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	*River-flat Eucalypt Forest in the Sydney Basin Bioregion*	All except non-offsettable grasslands	
849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	*Cumberland Plain Woodland in the Sydney Basin Bioregion*	All except non-offsettable grasslands	
850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*Cumberland Plain Woodland in the Sydney Basin Bioregion*	All except non-offsettable grasslands	
877 Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion	*Western Sydney Dry Rainforest in the Sydney Basin Bioregion*	All	
883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	*Castlereagh Scribbly Gum Woodland in the Sydney Basin Bioregion*	All	
1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	*Shale Sandstone Transition Forest in the Sydney Basin Bioregion*	All except non-offsettable grasslands	

PCT	NSW TEC	Condition state	Specific criteria – field verification
1800 Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	*Swamp Oak Floodplain Forest of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions*	All	

11.4.3 COMMONWEALTH-LISTED TECS

PURPOSE

Section 3.1 and 3.2 of the Terms of Reference requires the SAR to:

- Describe the nature of the environment within the Strategic Assessment Area, and other areas outside the Strategic Assessment Area that may be impacted by actions taken under the Plan. This must include the extent and quality of native vegetation, including mapping of Commonwealth-listed TECs
- Identify and describe each protected matter that may be impacted directly, indirectly and cumulatively by actions taken under the Plan, including:
    - Key sites
    - Condition, including seasonal and annual variability, and likelihood to alter over time

IDENTIFYING POTENTIALLY RELEVANT COMMONWEALTH TECS

Commonwealth TECs potentially present in the Strategic Assessment Area (see Table 11-8) were identified based on:

- The Australian Government's Protected Matters Search Tool
- Existing native vegetation mapping for the Cumberland Plain (OEH, 2013b, 2016b)
- Detailed native vegetation mapping undertaken within the nominated areas for this project

Table 11-8: EPBC Act TECs potentially relevant to the Plan

Commonwealth TEC	Commonwealth status
Blue Gum High Forest of the Sydney Basin Bioregion	CE
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	E
Coastal Swamp Oak (Casuarina glauca) Forest of NSW and South East Queensland ecological community	E
Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion	CE
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	CE
Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion	CE
River-flat Eucalypt Forest on Coastal Floodplains of southern NSW and eastern Victoria	CE
Shale Sandstone Transition Forest of the Sydney Basin Bioregion	CE
Turpentine-Ironbark Forest of the Sydney Basin Bioregion	CE
Western Sydney Dry Rainforest and Moist Woodland on Shale	CE

The general relationship between these TECs and PCTs is set out in Table 11-9.

Table 11-9: General relationship between Commonwealth TECs and PCTs

EPBC TECs	Associated PCTs	General relationship
Blue Gum High Forest in the Sydney Basin Bioregion	1237 Sydney Blue Gum – Blackbutt – Smooth-barked Apple moist shrubby open forest on shale ridges of the Hornsby Plateau, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)

EPBC TECs	Associated PCTs	General relationship
	958 Narrow-leaved Apple – Hard-leaved Scribbly Gum heathy woodland on sand at Agnes Banks, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland	1800 Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	PCT is largely equivalent to Commonwealth TEC (VIS database)
Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion	725 Broad-leaved Ironbark – Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	724 Broad-leaved Ironbark – Grey Box – Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
	849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
	850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
River-flat eucalypt forest on coastal floodplains of southern New South Wales and eastern Victoria	835 Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion	774 Coast Banksia scrub on sand in the Elderslie area, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
Shale Sandstone Transition Forest in the Sydney Basin Bioregion	1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to Commonwealth TEC (VIS database)
	1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion	PCT partially contains Commonwealth TEC (VIS database
Turpentine–Ironbark Forest of the Sydney Basin Bioregion	1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion	PCT is largely equivalent to Commonwealth TEC (VIS database)
	1284 Turpentine - Smooth-barked Apple moist shrubby forest of the lower Blue Mountains, Sydney Basin Bioregion	PCT partially contains Commonwealth TEC (VIS database
Western Sydney Dry Rainforest and Moist Woodland on Shale	830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	PCT is largely equivalent to Commonwealth TEC (VIS database)

EPBC TECs	Associated PCTs	General relationship
	877 Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion	PCT partially contains Commonwealth TEC (VIS database)

COMMONWEALTH TEC MAPPING METHOD

Within the nominated areas

The approach to identify and map Commonwealth-listed TECs within the nominated areas was broadly similar to the approach used to map NSW-listed TECs, but involved a number of additional steps which reflected the typically different listing definitions of the TECs. The approach involved:

Step 1: The updated native vegetation map (see Section 11.3) was used to identify areas of potential TECs on the basis of associations between PCTs and TECs (see Table 11-9)

Step 2: Rapid assessment ground-truthing was undertaken to contribute to the reliability of the desktop process. GIS consultants used this data to assist with assigning condition classes to the PCTs within the nominated areas

Step 3: PCTs were correlated with potential TEC types. Once the vegetation maps were updated, the PCTs were selected for further assessment against the EPBC TEC criteria

Step 4: To account for potential occurrence of DNG around treed patches of PCTs, polygons were buffered by 30 m and overlapping buffers were merged into single polygons

Step 5: A patch size was attributed to each polygon and distribution criteria for each potential TEC were applied to the polygons. Table 11-10 shows the distribution criteria and patch size criteria for each TEC with potential to occur within the nominated areas. Where a polygon did not meet the criteria, it was not considered further as an area of TEC

Step 6: Projected Foliage Cover (PFC) as assessed (where relevant to the TEC threshold criteria (see Table 11-10) and polygons not meeting the criteria were removed. This was done by:

- Reclassifying the canopy height model raster (derived from 1 metre LiDAR point cloud) to select vegetation pixels over 15 m tall to represent canopy trees
- Calculating the number of 1 m x 1 m tree pixels in each contiguous patch of vegetation
- Calculating the per cent canopy coverage by dividing the area covered by tree pixels by the total area of the polygons and multiplying by 100
- Calculating PFC by multiplying the per cent canopy coverage by 0.5
- Removing polygons that fell below the criteria for the TEC

Step 7: Where a TEC included elevation criteria, this was applied and polygons not meeting the criteria were removed. This was done by calculating the maximum elevation for each vegetation polygon (derived from 1 m LiDAR point cloud) and removing areas that fell outside the elevation threshold criteria

Step 8: Candidate TEC polygons were mapped. If a vegetation polygon satisfied the conditions in Steps 3-7, it was mapped as a 'candidate' TEC polygon, and Step 9 or Step 10 were undertaken to further classify the PCT

Step 9: Where plot data was available in a candidate TEC polygon, condition class criteria were applied to determine if the polygon met the definition of the TEC. The following steps were undertaken as part of this process:

- BAM plot data points were joined to TEC candidate polygons
- Condition class criteria for respective TECs were applied
- For polygons achieving all criteria, they were assigned to the respective TEC as 'known'
- For all other candidate polygons that did not meet the condition class criteria, they were removed from being considered a TEC

Step 10: Where plot data was not available in a candidate TEC polygon, they were categorised into 'high', 'moderate' or 'low' potential EPBC TEC based on the following parameters:

- High potential TEC – Intact veg with a patch size > 10 ha
- Moderate potential TEC – All veg conditions with a patch size > 1 ha
- Low potential TEC – All veg conditions with a patch size between 0.5-1 ha

Table 11-10 shows the rule set developed for identifying Commonwealth TECs.

Outside the nominated areas

The approach for TEC mapping outside the nominated areas within the Strategic Assessment Area used additional mapping sources and did not apply detailed criteria to the mapping models.

The approach involved:

Step 1: Potential areas of the TEC were identified from existing native vegetation maps. This involved:

- Combining the Cumberland Plain West vegetation mapping with SMCMA vegetation mapping into a single layer and clipping it to the Cumberland subregion
- Correlating PCTs with potential TEC types

Step 2: Distribution and patch size class criteria were applied. A patch size was attributed to each potential TEC polygon and polygons were filtered for distribution criteria. Where a polygon did not meet the criteria, it was not considered further as an area of TEC

Step 3: Condition class criteria were applied. This involved selecting potential TEC polygons for further consideration by sorting for the following condition classes in the vegetation mapping (OEH, 2013b, 2016b): A and B, and Low and Moderate condition classes respectively. These condition classes are the only ones considered likely to meet EPBC condition class criteria. This step was undertaken by GIS consultants

Step 4: Candidate TEC polygons were mapped. If a vegetation polygon satisfied the conditions in Step 3, it was mapped as a candidate TEC polygon. The candidates were based on the following parameters:

- High potential TEC – Intact veg with a patch size > 10 ha
- Moderate potential TEC – All veg conditions with a patch size > 1 ha
- Low potential TEC – All veg conditions with a patch size between 0.5-1 ha
- Not TEC

Justification of method

The mapping of Commonwealth-listed TECs is particularly challenging at the scale of the Strategic Assessment Area. It poses greater challenges to the mapping of NSW-listed TECs as Commonwealth-listed TECs are subject to additional key diagnostic characteristics and condition thresholds identified in conservation or listing advices that determine whether a patch of vegetation comprises the TEC. These criteria aim to focus protection on the most valuable patches, and generally exclude highly degraded patches of less value (DEWHA, 2009a). The method for mapping Commonwealth-listed TECs aimed to ensure these criteria were considered to the greatest extent possible with the data available.

Several criteria in the conservation or listing advices can be assessed through desktop methods using data such as high definition aerial imagery and LiDAR, as well as GIS tools. However, this process is limited by the accuracy of the input data, including the underlying vegetation mapping. The limitations of the vegetation mapping that underpins the Commonwealth-listed TEC mapping within the nominated areas is summarised in Chapter 13.

Within the nominated areas the vegetation mapping is considered to be reasonably accurate, as mapping was undertaken based on detailed desktop analysis as well as on-ground validation (see section 11.3).

Outside the nominated areas, the mapping is based on vegetation modelling and has not undergone the same degree of validation. In these areas, the process to determine candidate TEC polygons was subject to several assumptions and limitations relating to the accuracy of the vegetation mapping, the age of the LiDAR data, and the angle and aspect of the

aerial imagery used. These limitations were addressed where possible by testing the models that generated the TEC mapping based on desktop validation and making iterative updates to the models.

Other criteria in the conservation or listing advices relating to the condition or floristic composition and structure of the patch, can only be accurately determined from on-ground surveys. Where surveys were undertaken, this data was used to provide an accurate determination about whether a patch comprised a TEC. However, due to the large size of the Strategic Assessment Area and limited land access, many candidate TEC patches could not be validated on-ground. To address this limitation, assumptions about the condition of a patch were made at a desktop level based on the size of the patch, its likely resilience to degradation, and its likelihood of being edge effected.

To address the lack of certainty around patches of candidate TEC that could not be validated through on-ground surveys, all non-validated candidate TEC patches were assigned to a category reflecting the potential of the patch to comprise the TEC. This was based on the assumption that larger and better condition patches of vegetation that have satisfied the criteria for Steps 3 to 7 are more likely to meet the listing criteria for the TEC. This step was undertaken to provide transparency around the level of certainty in the TEC mapping and to provide the highest level of assurance possible around the potential impacts of the project on Commonwealth-listed TECs. For the purposes of the assessment all 'known', 'high potential', 'moderate potential and 'low potential' polygons were considered to be the TEC.

It is important to note that the peer review (see Section 10.4) concluded that the Commonwealth-listed TEC mapping method is generally conservative and likely to over-predict the distribution of TECs in the Strategic Assessment Area.

RESULTS

Nine of the ten potentially relevant TECs were determined to be present in the Strategic Assessment Area. *Blue Gum High Forest in the Sydney Basin Bioregion* was found not to be present and was not assessed further.

The results of the mapping for Commonwealth-listed TECs are provided in Chapter 31.

Table 11-10: Rule set for mapping Commonwealth-listed TECs within the nominated areas

PCT no.	Commonwealth TEC	Distribution/ patch size class criteria (See Step 5 of the mapping method within the nominated areas)	Specific condition class criteria (See Steps 6 and 7 of the mapping method within the nominated areas)
883 958	*Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion*	Patch size ≥ 0.5 ha AND greater than 30 per cent (and less than 50 per cent) of the perennial understorey vegetation cover is made up of native species (field verification) AND the patch is contiguous with a native vegetation remnant > 1 ha in area AND Growing on tertiary sands and gravels of the Hawkesbury-Nepean river system	Greater than (or equal to) 50 per cent of the perennial understorey vegetation cover is made up of native species A low woodland, with canopy species reaching an average 15 m in height, but with some trees growing to around 20 m
		Patch size ≥ 0.5 ha AND Greater than (or equal to) 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Patch is contiguous with a native vegetation remnant > 1 ha in area AND Elevations below 80 m AND Growing on tertiary sands and gravels of the Hawkesbury-Nepean river system AND greater than 30 per cent (and less than 50 per cent) of the perennial understorey vegetation cover is made up of native species	A low woodland, with canopy species reaching an average 15 m in height, but with some trees growing to around 20 m
1800	*Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community*	Patch size ≥ 5 ha OR Patch size at least 2 ha and < 5 ha OR Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha AND Non-native species comprise less than 20 per cent of total understorey vegetation cover	Non-native species comprise less than 50 per cent of total understorey vegetation cover
		Patch size ≥ 5 ha OR Patch size at least 2 ha and < 5 ha OR Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha AND Non-native species comprise less than 50 per cent of total understorey vegetation cover	Non-native species comprise less than 50 per cent of total understorey vegetation cover AND transformer species* comprise less than 30 per cent of total understorey vegetation cover

PCT no.	Commonwealth TEC	Distribution/ patch size class criteria (See Step 5 of the mapping method within the nominated areas)	Specific condition class criteria (See Steps 6 and 7 of the mapping method within the nominated areas)
725	*Cooks River / Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	Patch size greater than or equal to 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone 150° 51′ 38″E) AND Greater than or equal to 30 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Below 100 m elevation AND Rainfall 800-1000 mm pa AND Growing on Clay rich soils derived from tertiary alluvium and on Wianamatta derived shale soils found next to tertiary alluvium AND the patch is contiguous with a native vegetation remnant > 1ha OR the patch has at least one tree with hollows or at least one large locally indigenous tree (> 80 cm diameter at breast height) (field verification)	Greater than or equal to 50 per cent of the perennial understorey vegetation cover is made up of native species
		Patch size ≥ 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone 150 51′ 38″E) AND Greater than or equal to 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Below 100 m elevation AND Rainfall 800-1000 mm pa AND Growing on clay rich soils derived from tertiary alluvium and on Wianamatta derived shale soils found next to tertiary alluvium	Consistent canopy, mid and ground strata layers in accordance with the listing advice species composition Greater than or equal to 30 per cent of the perennial understorey vegetation cover is made up of native species Where patch is not contiguous with a native vegetation remnant >1 ha, patch must have one tree with hollows or at least one large locally indigenous tree (>80 cm diameter at breast height)
724 849 850	*Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest*	Patch size ≥ 0.5 ha AND > 50 per cent perennial understorey vegetation made up of natives (field verification) OR patch size ≥ 5 ha AND > 30 per cent perennial understorey made up of natives (field verification) AND Below 350 m elevation AND Growing on clay soils derived from Wianamatta	Canopy cover greater than 10 per cent For patches greater than 0.5 ha native understorey cover is greater than 50 per cent OR for patches greater than 5 ha, native understorey cover is greater than 30 per cent

PCT no.	Commonwealth TEC	Distribution/ patch size class criteria (See Step 5 of the mapping method within the nominated areas)	Specific condition class criteria (See Steps 6 and 7 of the mapping method within the nominated areas)
		Patch size ≥ 0.5 ha AND > 30 per cent native understorey (field verification) AND is contiguous with a native vegetation remnant ≥ 5 ha OR patch size ≥ 0.5 ha AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥ 80 centimetre diameter at breast height) per ha (field verification). AND Below 350 m elevation AND Growing on clay soils derived from Wianamatta	Native understorey cover is greater than 30 per cent AND/OR at least one tree with at least one tree with hollow per ha or at least one large tree (≥ 80 centimetre diameter at breast height) per ha Consistent canopy, and either mid and/or ground strata layers in accordance with the listing advice species composition
774	*Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion*	Due to the very small size of patches and extent remaining and the nature of the threats, condition thresholds have not been applied to the Elderslie Banksia Scrub Forest ecological community. All remaining patches are considered critical to the survival of this ecological community (DAWE, 2020).	Based on the adjacent advice from the TEC's Conservation Advice no specific criteria have been used to map the occurrence of this community. The presence of the TEC has been mapped based on the presence of PCT 774 only.
835	*River-flat eucalypt forest on coastal floodplains of southern New South Wales and eastern Victoria*	Patch size ≥ 0.5 ha and not within a larger area of native vegetation' ≥5ha AND > 50 per cent perennial native understorey AND > 6 native ground cover species present AND > 10 large trees per hectare OR Patch size is ≥ 0.5ha is within a larger area of native vegetation ≥ 5ha OR patch size is > 2ha AND > 30 per cent perennial native understorey AND > 4 native ground cover species present	Native understorey cover is greater than 30 per cent (dependent on size of patch) AND/OR at least one tree with at least one large tree per plot AND/OR at least 4 native ground cover species present per plot (dependent on size of patch) Consistent canopy, and either mid and/or ground strata layers in accordance with the listing advice species composition

PCT no.	Commonwealth TEC	Distribution/ patch size class criteria (See Step 5 of the mapping method within the nominated areas)	Specific condition class criteria (See Steps 6 and 7 of the mapping method within the nominated areas)
1395 1281	*Shale Sandstone Transition Forest in the Sydney Basin Bioregion*	Patch size ≥ 0.5 ha AND > 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) OR patch size ≥ 2 ha AND > 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Rainfall 800-1100 mm pa AND Growing on Shale or sandstone soil substrates	Consistent canopy, mid and ground strata layers in accordance with the listing advice species composition Where patch size is 0.5–2 ha, native understorey cover is greater than 70 per cent OR where patch size is greater than 2 ha, native understorey cover is greater than 50 per cent
		Patch size ≥ 0.5 ha AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥ 80 centimetre diameter at breast height) per ha OR the patch is contiguous with a native vegetation remnant ≥ 1 ha (field verification) OR patch size ≥ 0.5 ha and > 50 per cent perennial understorey vegetation made up of natives (field verification) AND Rainfall 800-1100 mm pa AND Growing on Shale or sandstone soil substrates Some areas of regrowth intact woodland	Where patch size is greater than 0.5 ha, native understorey cover is greater than 50 per cent OR where patch size is greater than 0.5 ha, native understorey cover is greater than 30 per cent and patch is not contiguous with another remnant greater than 1ha, at least one tree with hollows per ha or at least one large tree (≥ 80 cm diameter at breast height) per ha
830 877	*Western Sydney Dry Rainforest and Moist Woodland on Shale*	Patch size ≥ 0.1 ha AND at least 20 native species present in sample 0.04 ha plot AND non-native perennial plants no more than 50 per cent of total vegetation cover (field verification) AND Below 300 m elevation AND Growing on clay soils derived from Wianamatta	At least 20 native species present in sample 0.04 ha plot AND non-native perennial plants no more than 50 per cent of total vegetation cover

Table 11-11: Rule set for mapping Commonwealth-listed TECs outside the nominated areas

PCT no.	Commonwealth TEC	Condition Class	Distribution criteria – GIS
1237	*Blue Gum High Forest in the Sydney Basin Bioregion*	A or B Low and moderate	Patch size > 1 ha
			Patch size > 1 ha AND occurs in areas of native vegetation in excess of 5 ha
883 958	*Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion*	A or B Low and moderate	Patch size ≥ 0.5 ha AND Patch is contiguous with a native vegetation remnant > 1 ha in area
			Patch size ≥ 0.5 ha AND the patch is contiguous with a native vegetation remnant > 1 ha in area
1800	*Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community*	A or B Low and moderate	Patch size ≥ 5 ha OR Patch size at least 2 ha and < 5 ha OR Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha
725	*Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	A or B Low and moderate	Patch size ≥ 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone (150◎ 51′ 38″E))
			Patch size greater than or equal to 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone (150° 51′ 38″E)) AND the patch is contiguous with a native vegetation remnant > 1ha OR the patch has at least one tree with hollows or at least one large locally indigenous tree (> 80 cm diameter at breast height) (field verification)
724 849 850	*Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest*	A or B Low and moderate	Patch size ≥ 0.5 ha AND > 50 per cent perennial understorey vegetation made up of natives (field verification) OR patch size ≥ 5 ha AND > 30 per cent perennial understorey made up of natives (field verification)
			Patch size ≥ 0.5 ha AND > 30 per cent native understorey (field verification) AND is contiguous with a native vegetation remnant ≥ 5 ha OR patch size ≥ 0.5 ha

PCT no.	Commonwealth TEC	Condition Class	Distribution criteria – GIS
			AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥ 80 cm diameter at breast height) per ha (field verification)
1395 1281	*Shale Sandstone Transition Forest in the Sydney Basin Bioregion*	A or B Low and moderate	Patch size ≥ 0.5 ha AND > 70 per cent of the perennial understorey vegetation cover is made up of native species (field verification) OR patch size ≥ 2 ha AND > 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification)
			Patch size ≥ 0.5 ha AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥80 centimetre diameter at breast height) per ha OR the patch is contiguous with a native vegetation remnant ≥1 ha (field verification) OR patch size ≥ 0.5 ha and > 50 per cent perennial understorey vegetation made up of natives (field verification)
1281 1284	*Turpentine–Ironbark Forest of the Sydney Basin Bioregion*	A or B Low and moderate	Patch > 1 ha AND tree canopy cover > 10 per cent (field verification)
			Patch > 1 ha AND tree canopy cover < 10 per cent (field verification) AND part of a remnant of native vegetation > 5 ha
830 877	*Western Sydney Dry Rainforest and Moist Woodland on Shale*	A or B Low and moderate	Patch size ≥ 0.1 ha

*Transformer species (e.g. *Chrysanthemoides monilifera, Asparagus* spp, *Pennisetum* spp, *Ipomoea* spp. etc.) are non-native plant species with the potential to permanently change the character, condition, form or nature of patches of the ecological community.

11.5 THREATENED SPECIES

11.5.1 OVERALL APPROACH TO SPECIES MAPPING

To meet the requirements of the BAM and the ToR, species habitat maps have been prepared for all:

- NSW-listed candidate SCS within the nominated areas – these species habitat maps represent the 'species polygons' as required by the BAM
- Commonwealth-listed Category 1 species within the Strategic Assessment Area

The BAM does not require mapping of habitat for NSW-listed ECS, as these species are associated with specific PCTs and their presence in these PCTs is assumed for the purposes of the BAM.

Different mapping methods were applied within the nominated areas and outside the nominated areas within the Strategic Assessment Area, as well as to NSW-listed candidate SCS and Commonwealth-listed Category 1 species because of the different requirements of the BAM and ToR.

In some cases, a species habitat map was prepared for a Commonwealth-listed Category 1 species within the nominated areas in accordance with the requirements of the BAM because the Commonwealth species is also a NSW-listed species. In these cases, the nominated areas BAM species habitat map was integrated into the species habitat map for the remainder of the Strategic Assessment Area and formed the basis of the assessment of impacts on that species.

Table 11-12 summarises the species habitat mapping methods within and outside the nominated areas for NSW-listed candidate SCS and Commonwealth-listed Category 1 species.

Table 11-12: Summary of mapping approaches for NSW and Commonwealth-listed species

Species	Mapping area	Mapping method
NSW-listed candidate SCS	Nominated areas	Species polygons, either based on: • Expert reports, or • Assumed presence based on potential habitat maps created using a knowledge-based method, refined by ground validation surveys
Commonwealth-listed Category 1 species	Strategic Assessment Area	• Species Distribution Modelling, where species records are adequate, or • Assumed presence using a knowledge-based method (without refinement from ground-validation surveys), where species records are not adequate to generate a Species Distribution Model
		For Commonwealth-listed species that have habitat maps prepared within the nominated areas (because they are also NSW-listed), the maps incorporate the nominated area mapping (e.g. including any expert report polygons) to ensure use of best available data

11.5.2 NSW-LISTED SPECIES

PURPOSE

Section 6.4.1.26 of the BAM requires species polygons are prepared for each NSW-listed candidate SCS within the nominated areas, where either:

- A survey or expert report confirms a SCS is present or likely to use suitable habitat, or
- A SCS is assumed to be present

A species polygon must be used to identify:

- The location of suitable habitat for each species
- The area of suitable habitat, or number of individuals within suitable habitat, for each species
- The condition of the suitable habitat (for species assessed based on area of suitable habitat)

METHOD

Species polygons for NSW-listed candidate SCS were prepared using either:

- Expert reports, or
- Assumed presence, based on potential habitat maps created using a knowledge-based method, refined by ground validation species or habitat presence/absence surveys

It is important to note that both methods resulted in species polygons that reflect potential habitat within the nominated areas. Potential habitat represents areas where a species may occur, but is not necessarily known to occur.

These species polygons are based largely on data that has not been ground-validated due to very large size of the assessment area and land access constraints. As such, habitat associations are based on broad relationships between species and PCTs, vegetation condition, and other landscape scale features and cannot consider the presence of specific habitat components, or levels of habitat degradation, that may support/preclude the presence of actual species habitat.

These species polygons are therefore considered highly conservative in areas where ground-validation surveys were not possible and are likely to greatly overestimate the area of actual habitat for each species.

Table 11-13 summarises the mapping method used for each NSW-listed candidate SCS.

Table 11-13: Summary of mapping method used for NSW-listed candidate SCS

Species	Assumed presence refined using a knowledge-based method	Expert report	Expert report author
Acacia bynoeana	-	Yes	Dr Steven Douglas
Acacia pubescens	-	Yes	Dr Steven Douglas
Allocasuarina glareicola	Yes	-	-
Callocephalon fimbriatum	Yes	-	-

Pultenaea pedunculata	Yes	-	-
Tyto novaehollandiae	Yes	-	-

* It should be noted that the species polygons for Swift Parrot are based on the species' Important areas mapping produced by DPIE, and as such the species was not subject to either "Assumed presence refined using a knowledge-based method" or the use of an "Expert report"

Expert reports

This method was used to prepare species polygons for species where expert reports were prepared. The expert reports were prepared in accordance with Section 6.5.2 of the BAM and are provided in Supporting Document C.

Expert reports were prepared for species that:

- Could not be sufficiently surveyed for due to either access restrictions, seasonality or their cryptic nature
- Had highly specific habitat requirements and restrictions, or highly generalist habitat associations, for which expert advice was required to accurately assess and map

Table 11-13 shows the NSW-listed candidate SCS for which expert reports were prepared and their author.

Initially a workshop was held with Biosis, Open Lines, and EcoPlanning to ascertain which candidate species required expert reports. This process was guided by regionally available vegetation mapping, BioNet records, and the candidate species lists generated for each of the nominated areas.

All available data on biodiversity values of the nominated areas was made available to the experts, including data on initial surveys undertaken by the consulting team in 2017-2018 (see under 'targeted surveys' below).

The experts conducted further surveys within the nominated areas where access was possible (this is outlined in each report). The methods and assumptions used to map species habitat for each species, and the credentials of the expert who prepared the report, is provided in each expert report (see Supporting Document C).

Final reports for all 14 species were provided by the experts to the Department and the consulting team by early 2019.

Updates to expert report species polygons

Following finalisation of the expert reports in 2019, several updates to baseline datasets were made, which meant that subsequent updates were required to the expert report species polygons. These updates to data were a result of:

- Ongoing fieldwork undertaken over the course of the project including the collection of BAM plots and detailed vegetation community surveys of areas where new access became available, which resulted in updates to the vegetation mapping
- Undertaking additional targeted species ground validation surveys within the nominated areas in winter and spring 2019 (see under 'targeted surveys' below) to confirm the presence or absence of threatened species, and/or suitable habitat, in locations where access had previously been limited
- Updating native vegetation mapping (see Section 11.3.2) following public exhibition. Native vegetation mapping in the nominated areas was updated where landholders provided evidence in submissions as part of the public consultation process to support changes to the mapped vegetation on their properties. These updates are relevant to species habitat mapping as the vegetation mapping forms the basis of the threatened species habitat mapping

Additional targeted species ground validation surveys were used to ground-truth and refine species polygons, including the expert report species polygons. Areas were excluded from the species polygons where either:

- For fauna and some flora – the specific habitat components or microhabitats required by the species were found not to be present or substantially degraded (in accordance with BAM Section 6.4) within the area surveyed, or
- For flora – the species was not detected (in accordance with BAM Section 6.5) within the area surveyed during the specific survey periods as outlined in BioNet

Further detail on how ground surveys were used to refine species polygons is provided below.

In relation to the updates to native vegetation mapping, Biosis ecologists re-applied the rule-sets detailed in the expert reports that identified the PCTs and any condition thresholds associated with habitat for a species, as well as any other relevant ecological data used. Where the updated native vegetation mapping changed the PCT and/or condition of an area mapped as potential habitat by the expert, the species polygon was changed to suit (for example, the species polygons were amended for a species where the PCT in a specific location changed to a PCT that is not associated with habitat for the species according to the rule-set in the expert report).

Following these updates to species survey data and native vegetation mapping, Biosis prepared initial draft updates to the expert report species polygons for consultation with the experts. Biosis engaged with each expert to outline the process undertaken to update the mapping. Experts were given the opportunity to review the additional species survey data and updated native vegetation mapping and the draft updated species polygons. Biosis liaised with the experts via phone calls and emails, as well as web portal and video-conference workshops in March 2021, to take each expert through the updates and rationale for changes to the species polygons. Species experts endorsed the changes made to their species polygons based on the process outlined above, with the exception of:

- *Acacia pubescens*
- *Acacia bynoeana*
- *Hibbertia fumana*
- *Hibbertia puberula*

It should be noted that the experts for these species did endorse updates to species polygons based on changes to the native vegetation mapping and evidence of habitat degradation.

No updates were made to species polygons developed for *Pimelea spicata* either as a result of targeted survey or following updates to vegetation mapping, as consultation with the species expert was not possible.

Assumed presence refined using a knowledge-based method

Description of knowledge-based method approach

All candidate SCS not subject to an expert report were assumed present under Section 6.4.1.21 of the BAM, as complete survey to determine species' presence/absence, and/or species' habitat constraints or habitat degradation, was not possible due to the very large size of the project area and associated land access constraints.

Species polygons were developed for all SCS assumed present as required by Section 6.4.1.26 of the BAM, which involved the application of a knowledge-based method. Section 6.4.1.30 of the BAM specifies that where a species is assumed to be present, the assessor must develop a species polygon which encompasses the entire vegetation zone/s within which the candidate species is predicted to use/occur, based on application of Step 1 to Step 4.

To ensure that species were not being assumed present over parts of the very large assessment area where they would not naturally occur, and to make use of best available ecological data, additional habitat parameters were considered to refine the species polygons. This inclusion of additional habitat parameters into the species polygons, coupled with ground validation surveys outlined below, has been termed the 'knowledge-based method'.

Developing species polygons using the knowledge-based method involved the following steps:

- Creating initial species polygons for each SCS assumed present based on BioNet PCT associations and the project specific vegetation condition states each species was considered likely to occur within (i.e. the vegetation zones within which each species was considered likely to occur, as per Section 6.4.1.30 of the BAM)
- Additional information about habitat parameters for each species drawn from information in BioNet or published, peer-reviewed literature as prescribed by Section 6.1.1.2 of the BAM was used to refine each species polygon
- Results of targeted surveys undertaken for the project (see section 'targeted surveys' below) to further refine several of the species polygons where the species (or its habitat) was/was not recorded within the mapped areas of habitat

The habitat parameters applied to the GIS model to refine the species polygons are provided in Attachment B.

For some species no data was available that could be used to refine the GIS models and several initial species polygons were based solely on PCT and vegetation condition association, including for Eastern Pygmy-possum and *Epacris purpurascens* var. *purpurascens*. Surveys were used to refine the final species polygons for these species. Several species were not able to be surveyed to a sufficient confidence level to refine species polygons based on the surveys (see below). These included Green and Golden Bell Frog, *Pimelea spicata* and Large-eared Pied Bat.

The four key steps in preparing species polygons were:

Step 1: Collate information on records and habitat parameters to establish species profiles for each species. The following information and datasets were used to collate species profiles:

- DAWE Protected Matters Search Tool and Species Profile and Threats Database
- BioNet Atlas and Threatened Biodiversity Data Collection
- PlantNET
- BirdLife Australia, the New Atlas of Australian Birds 1998-2015
- BioNet Vegetation Classification database (OEH, 2018a)
- Remnant Vegetation of the Western Cumberland Subregion 2013 Update VIS_ID 4207 (OEH, 2013b)
- Native Vegetation of the Sydney Metropolitan Area VIS_ID 4489 (OEH, 2016b)
- Catchment Boundaries of New South Wales dataset
- NSW (Mitchell) Landscapes Version 3.0
- State Environmental Planning Policy (SEPP) Coastal Management
- NSW Soil and Land Information System (SALIS)
- Soil Landscapes of the Sydney, Penrith and Wollongong-Port Hacking 1:100 000 map sheets (Bannerman & Hazelton, 1990; Chapman & Murphy, 1989; Hazelton & Tille, 1990)

- Handbook of Australian, New Zealand and Antarctic Birds (Higgins, 1999)
- Conserving Koalas in Wollondilly and Campbelltown LGAs (DPIE, 2019)
- Terrestrial Vertebrate Fauna of the Greater Southern Sydney Region Volume 2 (DECC, 2007)
- Cumberland Plain Recovery Plan (DECCW, 2011)
- Threatened ecological community determinations, conservation advices and listings
- BirdLife Australia shorebird data
- Topographic information
- Multiple species specific peer reviewed literature articles

Step 2: Prepare initial species polygons by assuming presence for each species based on the relevant PCT and condition class for the species identified in BioNet (i.e. all vegetation zones that the species is predicted to occur within under the BAM) and the updated native vegetation maps

Step 3: Refine initial species polygons prepared under step 2 based on the habitat parameters detailed within the species profiles collated in step 1, as well as data on species records, in approach that mirrors that prescribed in BAM Section 6.1.1.2. Habitat parameters included items that could be used to spatially restrict the GIS models used to develop the species polygons, and included items such as a restriction on patch size, proximity to waterways, associations with soil types/boundaries, tree heights (determined using LiDAR data - see Attachment B, Section B.5 for further details on the LiDAR data used for species polygons), etc. The habitat parameter rule-sets built from the species profiles used to refine the initial species polygons are provided for each species in Attachment B

Step 4: Integrate results from targeted ground validation surveys (see further detail below) within the nominated areas. The results of the ground validation surveys were used to further refine the species polygons prepared under Step 2 and Step 3. The species polygons were updated by excluding surveyed areas from the polygon where either:

- For fauna and some flora – the specific habitat components required by the species (tree hollows, leaf litter / woody debris, stick nests, undisturbed ground layer etc.) were found to be absent from the area surveyed, or
- For flora – the species was not detected within the area surveyed

It is important to note that where flora species were recorded or where species' specific habitat requirements were confirmed present, the species polygon was either maintained or increased if the species or their habitat requirements were found to occur in areas not previously mapped (either by the species experts or based on species polygons).

Flora surveys undertaken during winter and spring 2019 were undertaken along predetermined parallel transect lines separated by 30 m. Where parallel transect lines were not appropriate (for example in areas of non-linear or patchy/sporadic habitat), targeted meander surveys were undertaken, targeting specific areas of mapped habitat.

It is acknowledged that for some targeted species (those species with smaller plant growth forms, such as orchids and herbs), the separation distance between transects of 30 m was greater than that specified by the *NSW Guide to Surveying Threatened Plants* (OEH, 2016a) and *Surveying threatened plants and their habitats* (DPIE, 2020c). The *NSW Guide to Surveying Threatened Plants* requires transects to be separated from between 10 m for the smallest plant growth forms (in open vegetation) and 40 m for the largest growth form plants (in open vegetation).

Justification for using increased (30 m) transect separation widths is provided below.

The results of species surveys undertaken earlier in the project (November 2017 to November 2018) were also used to further refine species polygons as outlined above, however a slightly different rule set was applied to areas surveyed. This was done by classifying habitat into high, moderate or low quality for each species based on native vegetation condition, and applying the following buffers to survey tracks depending on the classification:

- Trees:
  - High (Intact): 40 m either side of the transect line
  - Moderate or Low (Thinned, Scattered Trees, DNG): 40 m either side of the transect line
- Shrubs, herbs, forbs, grasses, other:
  - High (Intact): 20 m either side of the transect line
  - Moderate or Low (Thinned, Scattered Trees, DNG): 40 m either side of the transect line

The final species polygons reflect the initial species polygons created in Step 2, refined by habitat parameters through the application of Step 3, and further refined by the results of ground validation surveys as outlined in Step 4. The final species polygons represent areas of habitat where either:

- In areas not subject to ground validation surveys, the species was assumed present based on the habitat parameters used to develop the species polygon in Step 3, or
- In areas subject to ground validation surveys, the species or its habitat was confirmed present

Justification for knowledge-based method approach

Preparing species polygons using a knowledge-based method approach was undertaken because of a desire to use the best available information for each species – PCT associations, habitat parameters where they can be justified based on BioNet or published, peer-reviewed literature, and targeted surveys – to ensure species polygons are as accurate and meaningful as possible. The approach was undertaken considering Section 6.1.1.2 of the BAM, which specifies that:

> *'An assessor may use additional information about a threatened species, in BioNet (e.g. the profile of a threatened species) or published, peer reviewed literature, when assessing the habitat suitability of a site*

This approach is considered appropriate in the context of the very large size of the assessment area. It was not possible to determine whether each species is likely to use suitable habitat over the entirity of on the subject land or specific vegetation zones (Section 6.4.1.21 of the BAM) or prepare species polygons based on surveys (Section 6.4.1.26 of the BAM) due to the size of the assessment area and land access constraints (see Chapter 14). Surveys were restricted to sites where access was granted by landholders and these limitations meant it was not possible to survey either all vegetation polygons within a vegetation zone, or the entire subject land to prepare a species polygon.

An alternative to this approach under the BAM is to assume presence for each species across all relevant vegetation zones within which the species is predicted to occur. This would have led to extremely precautionary species polygons that are not informed by the best available information. The species polygons would therefore be less meaningful in assessing the impacts of the development on each species and determining offsets as part of the conservation program.

Furthermore, assuming presence of species in parts of the assessment area where they would not naturally occur has the potential to undermine the effectiveness of the process for avoiding and minimising impacts (see Chapter 14) (it creates a risk that avoidance effort is focused on less important areas of habitat for a species).

The knowledge-based method approach is consistent with that used to develop the Koala species polygons, which uses a combination of PCT associations, habitat requirements and surveys, to map koala habitat within the nominated areas. It is also consistent with the principles and approach for developing species polygons for species credit bat species (OEH, 2018e), which requires the consideration of microhabitats and landscape features such as waterways, caves and cliffs, and well as certain soil/geology associations, and the NSW *Survey Guide for Threatened Frogs* (DPIE, 2020b), which prescribes buffers from watercourses. Furthermore, it is consistent with the approach taken by a number of species experts where their subject species are restricted to certain sub-components of habitats rather than just PCT associations, *Pterostylis saxicola*, Green and Golden Bell Frog, *Pimelea spicata*, are all examples of this.

The approach is also considered suitable for flora species with restricted distributions, or those that are listed as endangered populations, which are associated with wide ranging PCTs. *Allocasuarina glareicola* (PCT 1081) and *Persoonia bargoensis* (PCT 849) are examples of where the assumption of presence across entire vegetation zones would potentially result in assumed impacts well outside the species' range (*Allocasuarina glareicola* in the southern nominated areas, *Persoonia bargoensis* in the northern nominated areas). Furthermore, if *Marsdenia viridiflora* subsp. *viridiflora* was assumed present across the entire PCT 849 and PCT 850 vegetation zones then impacts would be assumed in local government areas (south of Campbelltown) where the species is not known to occur.

There are many examples of threatened species where habitat polygons require refinements based on microhabitats, as outlined in the Threatened Biodiversity Data Collection, such as breeding habitat for dual credit species, and other individual species such as *Aldrovanda vesiculosa*, *Tetratheca juncea*, Common Planigale, Bristle-faced Free-tailed Bat, where the use of best available ecological data is required to refine the species polygons and calculation of impacts.

Justification for survey separation distances

For some flora species targeted during winter and spring targeted ground validation surveys (those species with smaller plant growth forms, such as orchids and herbs), the separation distance between transects of 30 m was greater than that

specified by the *NSW Guide to Surveying Threatened Plants* (OEH, 2016a) and *Surveying threatened plants and their habitats* (DPIE, 2020c). This guideline requires transects to be separated from between 10 m for the smallest plant growth forms (in open vegetation) and 40 m for the largest growth form plants (in open vegetation).

Justification for using increased (30 m) transect separation widths in the context of this project includes:

- The very large size of the assessment area. Increased transect widths ensured greater survey coverage of mapped potential habitat. This was considered appropriate over an assessment area the size of this project
- Based on experience in the field for this project and the nature of the habitats being surveyed, the ecologists consider a high level of confidence has been achieved regarding targeted species presence/absence in surveyed areas, and that it likely that any larger populations were detected using transect widths of this size
- Species polygons were mapped based on assumed presence incorporating best available ecological data, or expert reports, and surveys were only used to refine species polygons by confirming presence / absence of species or habitats within the areas surveyed
- In areas of the species polygons not surveyed, the species presence remained assumed, and the conservative nature of the species polygons ensures that an underestimation of impacts to any species is highly unlikely, and that potential impacts to all potential populations have been adequately assessed under the BAM

Furthermore, when the 30 m transect widths are compared to the survey coverage prescribed in the 'Two-phase grid-based systematic survey approach for large areas' provided in *Surveying threatened plants and their habitats* (DPIE, 2020c) the method used covers substantially more area of potential habitat and can therefore be considered to achieve an equivalent or better outcome than that method. This is also the case when compared to surveying for plants that would usually require 10 m separated transects. For a 1 ha square (i.e. the internal square created by 4 x 100 m grid-intercept points), the grid method results in coverage of 1,600 m^2 (or 16% of 1 ha). When 3 x 10 m wide search areas are undertaken at 30 m separated transects, across a 100 m x 100 m (1 ha) square, 3,000 m^2 (30%) is covered. Coverage then increases for each larger growth form as the prescribed transect widths (and resultant search areas) increase.

Updates to species polygons

Following public exhibition of the assessment report, updates were made to native vegetation mapping (see Section 11.3.2) in the nominated areas. The mapping was updated where landholders provided evidence in submissions as part of the public consultation process to support changes to the mapped vegetation on their properties. Where the native vegetation mapping was updated following public consultation, Biosis updated the species polygons where relevant based on the process outlined in Step 2 and Step 3 above, and the habitat parameter rule-sets in Attachment B.

Targeted surveys

The BAM requires surveys for each candidate SCS in accordance with EES survey guidelines, including the *'Species credit' threatened bats and their habitats NSW survey guide for the Biodiversity Assessment Method* (OEH, 2018e), *Threatened species survey guidelines for Amphibians* (DECC, 2009) and *NSW Guide to surveying threatened plants* (OEH, 2016a). Where no survey guidelines exist, surveys must be undertaken using best practice methods.

Targeted surveys were focused within initial species polygons (see section 'Assumed presence using a knowledge-based method' above) within the urban capable land and transport corridors of the nominated areas.

The purpose of the targeted surveys was to:

- Refine species polygons (see 'Assumed presence using a knowledge-based method' above)
- Confirm the presence or absence of species and/or species' habitat

A total of approximately 2,190 ha of combined threatened species habitat was surveyed.

The species recorded during the surveys are identified in Attachment A.

Surveys were undertaken on all land where access was granted by landholders, in accordance with relevant EES survey guidelines where possible. Not all surveys were able to be undertaken in accordance with survey guidelines due to lack of access to land or seasonal constraints. This was addressed by:

- Preparing expert reports
- Assuming presence (see section 'Assumed presence using a knowledge-based method' above)

Initial surveys – 2017 to 2018

Initial surveys for flora and fauna were undertaken across each nominated area over a period of one year, between November 2017 and November 2018, by Biosis and Ecoplanning ecologists.

Each survey team comprised of a minimum of two people, including one Accredited BAM Assessor.

Winter and spring surveys – 2019

Following analysis by the ecological consulting team and consultation with EES, it was decided that further surveys were required. The purpose of these surveys was to confirm the presence or absence of species habitat, particularly in locations where access had been limited in the past and refine the species habitat maps based on these surveys (see sections 'Expert reports' and 'Assumed presence using a knowledge-based method' above). For the species polygons prepared by expert report, this process was undertaken in consultation with the experts.

Pre-survey workshops were held between the ecological consulting team and the Department in June 2019 to determine an approach to the survey work, prioritise species for survey, determine which species could be surveyed for immediately, and the locations where targeted surveys should be undertaken.

The approach to gaining land access included targeted letter correspondence, phone calls (where available) and door knocking. It was determined that two additional survey periods would be undertaken, a winter 2019 survey and a spring 2019 survey in order to cover the defined survey periods of the included targeted species under the BAM. These surveys included targeted flora searches as well as targeted fauna habitat assessments.

The survey locations of the winter and spring surveys were determined and prioritised based on a combination of:

- Land access availability
- Total area of target species potential habitat mapped on a property
- Total number of species with potential habitat mapped on a property
- Distribution of properties across the nominated areas, to gain a broader coverage

Broad priority locations were determined based on the above criteria, and the Department contacted landowners to arrange access for targeted surveys. Once permission was obtained, each survey day was planned to ensure maximum coverage of the Plan Area by grouping sites supported by multiple survey teams across the nominated areas. In addition to the Department contacting landowners to arrange access, Biosis also undertook a number of doorknocking surveys in an attempt to gain access to additional private properties located within the Plan Area.

The winter 2019 targeted surveys were undertaken between 29 June and 02 August 2019 by both Biosis and Ecoplanning ecologists. The spring 2019 targeted surveys were undertaken between 17 October and 17 December 2019 by Biosis ecologists. Each survey team comprised of a minimum of two people, including one Accredited BAM Assessor.

Fauna surveys

Survey effort for the initial targeted fauna surveys undertaken within the nominated areas is summarised in Table 11-14. Survey effort for the targeted fauna habitat assessments undertaken during the winter 2019 and spring 2019 surveys is included in Table 11-15 (winter 2019), and Table 11-16 (spring 2019).

The weather conditions during the initial targeted fauna survey period are summarised in Table 11-17.

Map 11-1 shows the locations of targeted fauna surveys within the nominated areas.

Table 11-14: Initial targeted fauna survey effort

Nominated area	Date	Survey type	Person Hours/trap nights	Target species	Weather
Wilton	15/08/2018	2 ha bird transect	1.25	Regent Honeyeater and Little Lorikeet	Fine

Nominated area	Date	Survey type	Person Hours/trap nights	Target species	Weather

Flora surveys

Targeted flora survey effort is summarised in Table 11-18 (initial targeted flora survey effort), Table 11-19 (winter 2019 targeted flora survey effort), and Table 11-20 (spring 2019 targeted flora survey effort).

Flora surveys were undertaken within each PCT and vegetation zone and extended up to 50 m into habitat adjacent to the edge of the urban capable land or transport corridors. Flora species included in winter and spring targeted surveys are detailed in Table 11-21.

Map 11-1 shows the locations of the targeted flora surveys within the nominated areas.

Table 11-18: Initial targeted flora survey effort

Nominated area	Date	Method	Combined area (ha) of habitat surveyed	Surveyor

* The initial survey period occurred from November 2017 to November 2018 with targeted species surveys within this period occurring according to applicable species survey timeframes.

RESULTS

The habitat maps of each NSW-listed candidate SCS are provided in Chapter 21.

11.5.3 COMMONWEALTH-LISTED SPECIES

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan. This includes:

- Identification of key sites and habitats
- Identification of important populations

METHOD

Habitat for Commonwealth-listed Category 1 species was mapped within the Strategic Assessment Area using either:

- Species Distribution Modelling (SDM) where species data is adequate, or

- Assumed presence using a knowledge-based method

In some cases, a map has been prepared for a Commonwealth-listed Category 1 species within the nominated areas in accordance with the BAM because the Commonwealth species is also a NSW-listed candidate SCS. In these cases, that nominated areas species map was integrated into the Strategic Assessment Area species map and formed the basis of the assessment of impacts on that species within the nominated areas.

Table 11-22 summarises the mapping method used for each Commonwealth-listed Category 1 species, and shows where any nominated area mapping has been integrated into the Strategic Assessment Area map for a Commonwealth species.

Table 11-22: Summary of mapping method used for Commonwealth-listed Category 1 species

Scientific Name	Nominated areas		Strategic Assessment Area	
	Expert report	Assumed presence using a knowledge-based method	SDM	Assumed presence using a knowledge-based method

Pterostylis saxicola	Yes			Yes
Pultenaea parviflora		Yes	Yes	
Rostratula australis				Yes

Species Distribution Modelling

SDM was undertaken for Commonwealth-listed Category 1 species within the Strategic Assessment Area where adequate species records were available to develop a model. SDMs were developed for 19 Commonwealth-listed Category 1 species (6 fauna species and 13 flora species).

SDMs are statistical models used to estimate the relationship between species records at sites and the environmental and/or spatial characteristics of those sites. Once this relationship has been estimated, the SDM can be used to predict other locations in the landscape where the species is likely to occur.

SDMs were developed using the software package 'Maxent'. Data required for the modelling included:

- Species records obtained from BioNet. During a review of the records, various errors were identified. Ecologists were engaged to review the records and amend or exclude those with errors.
- Twenty-one environmental predictors that were used to establish the relationships between species records at sites and the environmental and/or spatial characteristics of those sites. These included:
    - Native vegetation community (PCTs)
    - Soil type
    - Mean annual temperature
    - Mean annual radiation
    - Number of days per year with minimum temperature less than 2 degrees
    - Latitude
    - Distance to streams
    - Topographic position

An approach was developed to account for the different levels of bias likely to be present in the species records. This resulted in the development of three maps for each species with different assumptions regarding bias in the records, depicting the likelihood of occurrence for each species. These three maps were then combined to produce a single SDM for each species with three classes of occurrence for each species:

- Unlikely to occur – none of the three models predicted the species to occur
- Potential to occur – at least one of the three models predicted the species to occur
- Likely to occur – all three of the models predicted the species to occur

Details of the SDM method and the results of the mapping is provided in Supporting Document F.

Assumed presence using a knowledge-based method

Where adequate species records were not available, Commonwealth-listed Category 1 species within the Cumberland subregion were mapped on the basis of assumed presence using a knowledge-based method. This method is the same method applied to NSW-listed candidate SCS within the nominated areas (see Section 11.5.2). The habitat parameters for each species, including habitat associations with PCTs, are provided in Attachment B.

Important populations

The term 'important populations' refers to a concept applied under the EPBC Act to inform the assessment of impacts of actions, such as urban development, on matters of national environmental significance. Important populations are defined in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) (DoE, 2013) as:

> *Any population of a vulnerable species which meets the definition of an important population in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) as follows:*
>
> *'A population that is necessary for a species' long-term survival and recovery. This may include populations identified as such in recovery plans, and/or that are:*
>
> - *key source populations either for breeding or dispersal*
> - *populations that are necessary for maintaining genetic diversity, and/or*
> - *populations that are near the limit of the species range'*

For the purposes of the SAR, important populations are also defined as including any population of an endangered or critically endangered species. Under the EPBC Act, all populations of an endangered or critically endangered species are considered to be important for the survival and recovery of the species.

The following steps were undertaken to identify and map important populations for critically endangered, endangered and vulnerable Commonwealth-listed Category 1 matters:

Step 1: Development of criteria for defining important populations for vulnerable Commonwealth-listed Category 1 matters. The criteria and rationale for each criterion is provided in Table 11-23.

Step 2: For each species, BioNet records were analysed to define biological populations of the species. This analysis was undertaken by senior ecologists with knowledge and expertise in the ecology of each species. Where gene flow between two records is considered likely, the records were assigned to the one population. The ecologists took the following factors into account in determining whether gene flow is likely between records:

- Distance between individual flora records
- The presence of features or barriers that might limit demographic or genetic exchange
- Pollinator type and seed dispersal mechanism (where known)
- The continuity of patches of vegetation

Attachment C sets out the assumptions made in defining biological populations for each species.

Step 3: For critically endangered and endangered Category 1 matters:

- Describe and map each population (including identifying population sizes)

Step 4: For vulnerable Category 1 species:

- Collate the required data on each species as per the data sources in Table 11-23
- Apply the criteria in Table 11-23 to each species, using GIS analysis where necessary
- Describe and map each population (including identifying population sizes)

RESULTS

The habitat and important population maps for each Commonwealth-listed Category 1 species are provided in Chapters 29 and 30.

Table 11-23: Criteria for identifying and mapping important populations of vulnerable Commonwealth-listed Category 1 species

	Criteria	Rationale	Data sources
1	Any population of a species identified as a Serious and Irreversible Impacts (SAII) entity under the NSW BC Act	SAII entities have been identified under the NSW BC Act and meet one or more of the following principles: • Species in rapid rate of decline • Very small population size • Very limited geographic distribution • Unlikely to respond to management and therefore irreplaceable Populations of SAII entities therefore make a significant contribution to the conservation of the species	• Threatened Biodiversity Data Collection
2	A population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important	Consistent with the EPBC Act Policy Statement 1.1 (DoE, 2013)	• Recovery plans • Conservation advices • Final determinations
3	A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program	Species targeted by the Saving our Species program have been prioritised for conservation effort under a program that aims to maximise the chance of securing the greatest number of species in the wild. Therefore populations targeted under the NSW Saving our Species program could comply with the following EPBC important population criteria: • Key source populations either for breeding or dispersal • Populations that are necessary for maintaining genetic diversity, and/or • Populations that are near the limit of the species' range	• Saving our Species program conservation projects database
4	A population associated with a commitment made under the Sydney growth centres conservation program	These populations have been previously identified for conservation, have had significant resources attributed to their conservation and are subject to existing commitments under the Sydney growth centres conservation program and should therefore be considered important	• Sydney Growth Centres Strategic Assessment: Program Report (DECCW & DOP, 2010) • NSW *Threatened Species Conservation Act 1995* Order to confer biodiversity certification on the State Environmental Planning Policy (Sydney Region Growth Centres) 2006

	Criteria	Rationale	Data sources
5	Any population of a species that contains more than 20 per cent of the total population (total number of mature individuals in the species) or 20 per cent of the Area of Occupancy (AOO)* of that species	Significant contribution to the conservation of the species. Loss of any population that contains 20 per cent or more of the total population or AOO is justification for change in status from Vulnerable to Endangered under IUCN and EPBC Act criteria (IUCN, 2012)	• BioNet, site specific surveys
6	Any population of a species where the species has less than 10 known subpopulations	These are species that have very few populations. All known populations therefore make a significant contribution to the conservation of the species. Loss of any population of such a species would be significant	• BioNet, site specific surveys
7	Any population of a species that is a large population in the context of the ecology of that species, in the opinion of senior ecologists	Large populations are important from a genetic perspective. They typically will have sufficient genetic diversity, increased evolutionary potential, reduced inbreeding effects and increased probability of long-term viability and persistence	• BioNet, site specific surveys
8	Any population of a species within a conservation reserve (regardless of the number of plants or size, etc.)	These populations are important because they are more likely to be effectively managed and have a greater chance of persistence due to their occurrence in a conservation reserve, and therefore make a significant contribution to the conservation and recovery of the species. Conservation reserve refers to those that meet IUCN protected area categories I-IV	• BioNet, site specific surveys • National parks estate data • BioBank and stewardship site data
9	Any population of a species that is important for maintaining the Extent of Occurrence (EOO)^ of that species	Maintaining the full range of a species has a greater chance of retaining the variation within the species (a primary aim of biodiversity conservation). Populations at the extent of occurrence or that are outliers to the more general distribution are likely to contain genetic difference or capacity to persist in different environmental conditions that will provide the species ability to cope and respond to changes in the environment, such as climate change	• BioNet, site specific survey • Commonwealth database profiles/distribution mapping

*AOO is defined as the area within a species 'extent of occurrence' which is occupied by a taxon, excluding cases of vagrancy. The measure reflects the fact that a taxon will not usually occur throughout the area of its extent of occurrence, which may contain unsuitable or unoccupied habitats

^EOO is defined as the area contained within the shortest continuous imaginary boundary which can be drawn to encompass all the known, inferred or projected sites of present occurrence of a species, excluding cases of vagrancy

11.5.4 KOALA

Specific habitat mapping was undertaken for the koala. Three forms of habitat mapping were undertaken. They include:

- An SDM for the species across the Cumberland subregion
- Corridor habitat mapping to identify the species polygons for koala as required by the BAM
- Mapping of habitat critical to the survival of the species

In addition, a connectivity analysis was undertaken for part of the Southern Sydney population.

SPECIES DISTRIBUTION MODEL FOR THE CUMBERLAND SUBREGION

RMIT University was engaged to prepare SDMs for a total of nineteen EPBC listed species found within the Cumberland subregion (see Supporting Document F). As part of this assessment, an SDM was prepared for koalas.

The overall purpose of preparing the SDMs was to (Gordon & Koshkina, 2018):

- Provide context for detailed environmental impact analysis being undertaken within the nominated areas, such as through providing information about the relative importance of different areas of habitat within each nominated area compared to the rest of the subregion
- Assist in evaluating commitments by providing indicative information about the amount of habitat available for biodiversity offsetting
- Enable indicative impact assessment of transport corridors

The SDM for koalas was prepared through the following process (Gordon & Koshkina, 2018):

1. Species records for koalas within the Cumberland subregion were sourced from BioNet and examined. The following records were removed:
    - Erroneous/inaccurate records
    - Records which were *not* associated with native vegetation were also removed, as records outside of native vegetation were taken to represent dispersing male koalas outside of regular habitat areas following the breeding season, or of records of areas that previously supported vegetation that is no longer there
2. A range of environmental parameters associated with koala records were tested for their capacity to predict koala occurrence across the subregion. The parameters which were selected for use in the SDM were those which:
    - Performed well in predicting koala occurrence
    - Did not increase the risk of introducing bias into the model
3. The selected environmental parameters, in addition to koala records, were used as inputs to generate three different SDMs. Each SDM adopted a different modelling methodology which accounted for different types of bias which were likely to be present within the input data
4. The outputs of each SDM were correlated, and a final SDM map was produced with the following categories:
    - 'Unlikely to occur' – Locations where none of the SDM models showed the species occurring
    - 'Potential to occur' – Locations where at least one of the SDM models showed the species occurring. These areas are the most appropriate for assessing potential impacts on the target species
    - 'Likely to occur' – Locations where all three of the SDM models showed the species occurring. These areas are the most appropriate for targeting conservation actions such as offsetting

The results of the SDM mapping are provided in Part 6. Results show the presence of higher quality ('likely to occur') koala habitat in the south of the Cumberland Plain, with small areas of lower quality habitat ('potential to occur') occurring elsewhere in the subregion (predominantly to the north-west and west). Overall, results indicate that there is likely to be very little koala habitat available within the Cumberland subregion.

Despite there being few koala records within the Cumberland subregion, it is recognised that there is an abundance of koala records in close proximity to the boundaries of the Cumberland subregion. For instance, Gordon & Koshkina (Gordon & Koshkina, 2018) recognise that there are over 2,700 records of koalas within a 10 km buffer distance of the subregion boundary.

It is important to recognise that the SDM mapping only shows areas where koalas are likely to be present based on environmental predictors. It does not take into account other key considerations, such as connectivity, habitat quality, and minimum habitat patch sizes for population viability or presence of threats. The mapping is therefore indicative, showing the extent and distribution of potential habitat available within the subregion; it does not necessarily indicate which areas of habitat are the most important locations to conserve a species (Gordon & Koshkina, 2018).

CORRIDOR HABITAT MAPPING

The corridor habitat mapping built on the work of EES in mapping habitat around Wilton and GMAC (DPIE, 2019) and applied a consistent approach. Mapping was undertaken separately for:

- Wilton Growth Area (Wilton), Greater Macarthur Growth Area (GMAC) and buffer area
- Greater Penrith to Eastern Creek Investigation Area (GPEC) and Western Sydney Aerotropolis (WSA)

The methods for these two regions are described below.

Mapping method for Wilton, GMAC and buffer area

The mapping method for Wilton and GMAC (and buffer area) is driven by the "long-established association between the presence of koalas and vegetation that grows on higher fertility soils, such as shale or shale-transition soils" (DPIE, 2019).

There are five steps in the mapping method:

1. Map Koala habitat
2. Identify principal and supporting habitat
3. Identify movement corridors
4. Categorise corridors into primary, secondary and tertiary
5. Define important habitat

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)

The first four steps in the corridor habitat mapping method for Wilton and GMAC are consistent with the approach taken by EES (see below for details). The minor differences were:

- This method is based on more detailed and updated vegetation mapping that was generated through the BAM process within the nominated areas
- Minor changes to the wording of this method were applied to provide greater clarity
- Aside from the use of records, validation of high-quality habitat was not repeated for this method

The fifth step about defining important habitat was required by the BAM and was in addition to the EES report.

Spatial scope of the mapping

The spatial scope of the mapping for Wilton and GMAC was:

- The two nominated areas
- Connected habitat between them
- Habitat to the east to the edge of the Strategic Assessment Area
- West to Bargo, Tahmoor and Thirlmere

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)

The spatial scope of the mapping was largely consistent with the approach taken by EES. The EES mapping extends further to the east, into the Holsworthy area which is outside the Strategic Assessment Area, and slightly further to the west of Thirlmere and Bargo. The mapping for this Assessment Report includes a few smaller areas that were not mapped as part of the EES mapping, including a small area at Buxton and Holsworthy.

Step 1: Map Koala habitat

Using PCTs (see Table 11-24), Koala habitat within the two nominated areas was mapped into three categories:

- High quality habitat (HQH) = all shale and shale-enriched vegetation types with a dominant eucalypt canopy
- Moderate quality habitat (MQH) = Eucalypt-dominated riparian sandstone communities, rainforest communities on shale with some eucalypts present, and regenerating *Acacia* scrubs on shale. Note: based on the vegetation within Wilton and GMAC and the surrounding land in the Plan Area there are no PCTs that meet this definition of moderate quality
- Low quality habitat (LQH) = Low-fertility sandstone vegetation communities including heaths, heathy woodlands, swamps, and rocky woodlands

Table 11-24: PCTs and Koala habitat in Wilton and GMAC

PCT	HQH	MQH	LQH
830 - Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
835 - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
849 - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
850 - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
877 - Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion		Y	
883 - Hard- leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	Y		
1081 - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1105 - River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion		Y	
1181 - Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Y		
1292 - Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion			Y
1395 - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1790 - Red Bloodwood - Grey Gum - Stringybark open forest on enriched sandstone ridges of the western Woronora plateau and lower Blue Mountains	Y		
1800 - Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Y		

Within the buffer area (outside the nominated areas) the EES mapping was incorporated into the data layer without change. Some small areas around Buxton and Holsworthy were not mapped by EES but are within the Strategic Assessment Area. Within these small areas the best available vegetation mapping was used to map Koala habitat based on the PCTs mapped (Table 11-25).

Table 11-25: PCTs and Koala habitat in small buffer areas of Buxton and Holsworthy

PCT	HQH	MQH	LQH
724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Y		
830 - Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
835 - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
849 - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
850 - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
883 - Hard- leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	Y		
941 - Mountain Blue Gum - Thin-leaved Stringybark open forest on river flat alluvium in the Sydney Basin Bioregion	Y		
1081 - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1083 - Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux of the Sydney Basin Bioregion			Y
1181 - Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Y		
1292 - Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion			Y
1395 - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1780 - Sydney Peppermint / Coachwood - Water Gum open forest in protected sandstone gullies around Sydney and the Central Coast			Y
1787 - Red Bloodwood - Scribbly Gum - Stringybark open forest on sandstone ridges along the western side of the Woronora and Hornsby plateaus			Y
1789 - Smooth-barked Apple - Blackbutt - Red Bloodwood open forest in enriched sandstone gullies of the western Woronora plateau		Y	
1790 - Red Bloodwood - Grey Gum - Stringybark open forest on enriched sandstone ridges of the western Woronora plateau and lower Blue Mountains	Y		
1803 - Banksia - Needlebush - Tea-tree damp heath swamps on coastal sandstone plateaus of the Sydney basin			Y
1826 - Dwarf Apple - Banksia - Tea-tree - Hakea heath-woodland on the hinterland sandstone plateaus from southern Sydney to Mangrove Mountain			Y

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)

The EES report used vegetation communities to define habitat quality (refer to Section 3.3 of the EES report). The method used for this Assessment Report updates this by using PCT associations from the updated vegetation mapping (see Table 11-24 and Table 11-25 above).

Given the validation work that EES had done (refer to Section 3.4 of the EES report), further validation of high-quality habitat was not repeated as part of the process for this Assessment Report.

Step 2: Identify principal and supporting Koala habitat

Principal habitat is defined as HQH patches greater than 100 ha that contain Koala records.

The remainder of habitat is defined as "supporting".

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)

Step 2 of the method for this Assessment Report is included within a broader step of the EES report (refer to Section 3.5 of the EES report) relating to the delineation of koala movement corridors. It was separated in the method for this report for the sake of clarity.

The actual method in this Assessment Report for defining 'principal habitat' is the same as the EES report. However, the EES report uses different terminology and calls it 'core habitat'. This report does not use the term 'core' in order to avoid confusion with the Koala SEPP.

Step 3: Identify movement corridors

Movement corridors include:

- All principal habitat except for those patches of principal habitat that are separated by more than 1 km
- Smaller patches of HQH within 100 m of patches of principal habitat in corridors
- Patches of MQH or LQH that connect patches of principal habitat within corridors or are entirely within principal habitat in corridors
- Scattered trees where they are completely or largely contained within corridors

Movement corridors exclude:

- Patches of principal habitat that are separated by more than 1 km
- Patches of MQH or LQH peripheral to corridors
- Scattered trees peripheral to corridors

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)

Step 3 of the method for this Assessment Report is also included within a broader step of the EES report (refer to Section 3.5 of the EES report) relating to the delineation of koala movement corridors. It was separated in the method for this report for the sake of clarity.

The actual method in this Assessment Report for identifying movement corridors is the same as the EES report. However, some rewording has been done.

Step 4: Categorise corridors into primary, secondary and tertiary

Primary corridors are identified as:

- Movement corridors that include patches of principal habitat which are contiguous (gaps between trees <100 m) and together contain greater than 380 ha

Secondary corridors are identified as:

- Movement corridors that include patches of principal habitat separated by more than 100 m from scattered trees or other principal habitat
- Are narrow or have pinch points of less than 50 m wide
- Together contain between 100 ha and 380 ha of principal habitat
- Otherwise, if containing greater than 380 ha of habitat or are not narrow, secondary corridors are those that do not connect to primary corridors on both ends

Tertiary corridors are identified as:

- Patches of principal habitat not linked to primary corridors
- Together contain between 30 ha and 100 ha of principal habitat
- Do not connect to other corridors on both ends
- Otherwise, if containing greater than 100 ha of habitat, tertiary corridors are those that lead away from other corridors

After allocation of the above categories the mapping for the nominated areas was compared to the mapping completed by EES. Where discrepancies between the mapping were observed (due to the application of more subjective measures such as 'connecting at both ends') consideration was given to adopting the same categories as mapped by EES. In some circumstances the categorisation of the mapping within the nominated areas was updated to that applied by EES.

As stated above for areas outside the nominated areas the EES mapping was accepted without change, and the primary, secondary and tertiary corridors match those defined by EES. In addition, lands identified as potential restoration areas by EES were adopted within and outside the nominated areas.

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)Step 4 of the method for this Assessment Report is also included within a broader step of the EES report (refer to Section 3.5 of the EES report) relating to the delineation of koala movement corridors. It was separated in the method for this report for the sake of clarity.

The actual method in this Assessment Report for categorising corridors into primary, secondary and tertiary is the same as the EES report. However, some rewording has been done.

Step 5: Define important habitat

Important habitat comprises the species polygons for Koala. It is made up of primary, secondary and tertiary corridors.

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)

Step 5 of the method for this Assessment Report was required by the BAM and was in addition to the EES report.

The rationale for defining important habitat as primary, secondary and tertiary corridors is was considered appropriate as it identifies the areas that are critical to the long-term viability of koalas (primary corridors) and the areas (if enhanced) that would support the population (secondary corridors). Including tertiary corridors in important habitat ensures the mapping is precautionary and captures a broad definition of koala habitat.

This approach was discussed with EES at the time of preparing the method.

Mapping method for GPEC and WSA

The Koala habitat mapping method for GPEC and WSA is based on similar high-level concepts as the mapping for Wilton and GMAC. However, due to the general lack of records within the two nominated areas all habitat is mapped as 'supporting' habitat.

There are two steps in the mapping method:

1. Review Koala records to determine the importance of the two nominated areas for Koalas
2. Map supporting Koala habitat

Spatial scope of the mapping

The spatial scope of the mapping for this method included the GPEC and WSA boundaries.

Step 1: Review Koala records

The BioNet record database was examined to determine the likelihood that Koalas are present within GPEC and WSA. It is noted that there are high human population densities in both areas, particularly within GPEC, and therefore an absence of records likely reflects an absence of Koalas (as opposed to an absence of surveys). There are no records of Koalas within WSA, and only two Koala records within GPEC dated from 1990 (in Blackett and Oxley Park). A small number of records also occur in semi-rural areas north of GPEC, as follows:

- Two records dated from 1984/85 in the Londonderry locality
- One record is dated from 2006 and located in a biodiversity offset site near Colebee
- Three records are dated from 2018 and located to the west of Shanes Park

Further Koala records are located to the west of the GPEC and WSA, within and in proximity to areas of remnant vegetation associated with the eastern boundary of the Blue Mountains.

Whilst a small number of Koala records occur within and in the vicinity of GPEC and WSA, the scarcity of these records, and the length of time between sightings, suggests that Koalas are extremely rare within the locality, and that it is very unlikely that there is a persistent population in the locality. Instead, it is more likely that Koala sightings within these localities are of dispersing individuals travelling between areas of more suitable habitat.

Koala habitat mapping, consideration of threatening processes, and koala BioNet records all suggest that:

- It is very unlikely that suitable koala habitat is present within either GPEC or WSA
- It is likely that any koalas present within GPEC or WSA are dispersing between areas of more suitable habitat

It is therefore considered that any Koalas within the GPEC or WSA would likely constitute individuals which have dispersed from the Blue Mountains Koala population, as this is the closest habitat area which is known to support a self-sustaining and expanding population from which Koalas are known to disperse.

Based on this, it was determined that there was no principal habitat within the two nominated areas and any habitat that is present should be mapped as supporting.

Step 2: Map supporting Koala habitat

Supporting habitat within GPEC and WSA was mapped using the PCTs in Table 11-26. These PCTs were identified based on the presence of Koala feed trees and definition of HQH and MQH, as described above, or through the PCT associations listed in the TBDC.

Table 11-26: PCTs - Supporting Koala habitat GPEC and WSA

PCT No.	PCT Name
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion

PCT No.	PCT Name
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion
830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
835	Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion
850	Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley

Consistency with *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* (DPIE, 2019)

Mapping of koala habitat in GPEC and WSA is not included in the EES report as the areas do not relate to the Wollondilly and Campbelltown LGAs.

The mapping that was applied for this Assessment Report for GPEC and WSA was generally based on similar high-level concepts to the EES report. However, due to the lack of records all habitat within the two nominated areas was mapped as 'supporting' habitat.

It should be noted that the koala was excluded as a candidate SCS in GPEC and WSA (see Section 11.1.1 for context). This was determined on the basis of:

- Habitat mapping
- Consideration of threatening processes
- Consideration of distribution of koala records

HABITAT CONNECTIVITY MAPPING – GAPCLOSR

Mapping of habitat connectivity was undertaken using a GIS-based spatial analytical framework known as the Generalised Approach to Planning Connectivity at Local and Regional Scales (GAPCLoSR) (Biolink, 2018). The text below provides a high level summary of that work, and the full report should be read to understand the project.

GAPCLoSR enables examination of issues associated with landscape connectivity and fragmentation. However, it is noted that the model only considers the length and arrangement of dispersal pathways; it does not consider other important factors which impact corridor usage (such as corridor width). The model is therefore useful as a support tool which enables more detailed analysis.

GAPCLoSR takes into account two key factors:

- The ecological needs and movement characteristics of the target species (e.g. the key characteristics of preferred habitat, the distribution and extent of preferred habitat, the greatest distance of open ground which can be crossed by the target species and the total distance which can be moved across the landscape by the species)
- The extent to which the existing landscape enables, influences and/or impedes movement of the target species

The program was used to investigate three different scenarios:

- **Baseline (*status quo*):** This constituted an analysis of the distribution of current habitat patches and connectivity through the Plan Area
- **Scenario 1:** This constituted analysis in which clearing occurred within the urban capable footprint, and where Appin Road was upgraded to a multi-lane dual carriageway with wildlife fencing on the eastern side of the road
- **Scenario 2:** This constituted analysis in which clearing occurred within the urban capable footprint, and where Appin Road was upgraded to a multi-lane dual carriageway with wildlife fencing on the eastern side of the road, with a wildlife crossing in place at the Ousedale-Mallaty corridor

Methodology

The basic model process involves inputting of key landscape features, determining the capacity for koala movement across each landscape feature, and then analysing the spatial distribution of the overall landscape to determine the degree of connectivity and fragmentation across the Plan Area.

Mapping landscape features

Key landscape features within the model included:

- Transport infrastructure (e.g. roads and railway lines)
- Hydrology (drainage lines, canals, etc.)
- Vegetation cover (including Preferred Koala Habitat)
- Mining and quarrying
- Agricultural areas (grazing and horticulture)
- Urban, commercial and industrial areas

Preferred Koala Habitat (PKH) was determined through the following process:

1. Vegetation mapping data was sourced from EES and from publicly available NSW Government databases
2. Vegetation maps were analysed, and the following areas were removed from analysis as being non-suitable for koala habitat:
    - Cleared areas
    - Highly-disturbed areas
    - Areas of scattered trees
    - Areas where satellite imagery did not match the vegetation type
3. Remaining vegetation layers are all considered to be Preferred Koala Habitat (PKH)
4. Areas of PKH were then classified into different sub-categories based on the availability of Preferred Koala Food Trees[1] (PKFTs). The following classes were made:
    - Primary Koala Habitat – where primary PKFTs comprise the dominant or co-dominant overstorey species
    - Secondary Koala Habitat (Class A) – where primary PKFTs are a sub-dominant component of the overstorey species
    - Secondary Koala Habitat (Class B) – primary PKFTs are absent, but the vegetation type is dominated by one or more 'secondary' PKFT
    - Secondary Koala Habitat (Class C) – primary PKFTs are absent, but one or more 'secondary' PKFTs are present as a sub-dominant component of the overstorey species
    - Other – does not contain PKFT
5. Each vegetation class was then assigned a different movement cost as follows:

[1] These include the following: *E. moluccana, E. longifolia, E. punctata, E. viminalis, E. tereticornis*

- Where PKH (of any class) is within a 'habitat patch' (i.e. area of habitat >10ha, an area defined by the authors), there are no movement costs
- When PKH is present as a corridor, Primary Koala Habitat has no movement cost, and Secondary Class Habitat has an increasing scale of movement cost (with the least movement cost for Class A, and the highest movement cost for Class C)

Allocating resistance values to landscape features

Each landscape feature was then assigned a Percentage Resistance Value (PRV). This value refers to the effort or cost it takes for a koala to cross a particular land-use type or class.

The resistance of the Plan Area to koala movement was then calculated as follows:

1. A rasterised surface was produced from land use layers of the Plan Area
2. Each pixel was then assigned a dispersal cost for koalas to cross at each point. Dispersal costs were calculated through considering each of the land use layers present for each pixel
3. In instances where multiple land use layers intersected at a particular point, it was important to define which data layer took precedence over the other. The following outlines the precedence in terms of their cost value:
   a) Connectivity structures spanning roads, train lines and aqueducts
   b) Train lines and aqueducts
   c) Roads
   d) Hydrology
   e) Vegetation cover (including PKH and non-PKH)
   f) Urban / commercial / industrial / agricultural land uses
4. A Gap Crossing Layer of 220 m was applied as a buffer around all vegetation, which was taken to be the maximum distance that a koala would travel across an open area (based on Euclidian distance of all koala records within the region from the nearest patch of mapped vegetation)

Mapping habitat connectivity

The locations and importance of connectivity corridors through the Plan Area were then modelled as follows:

a) The PRV of each pixel was examined
b) The cumulative PRV cost of any potential pathway between habitat patches was calculated
c) If the cumulative PRV cost of any potential pathway between habitat patches exceeded a threshold value, then a pathway would not be formed

It is noted that this method for identifying connectivity corridors does not rely on the Euclidian distance between habitat patches, but instead considers how hostile the landscape is to movement.

HABITAT CRITICAL TO THE SURVIVAL OF THE SPECIES MAPPING

In order to address the requirements of the EPBC Act referral guidelines for the vulnerable Koala (DoE, 2014) a map was prepared to identify habitat critical to the survival of the Koala. This mapping was prepared by adapting the method proposed in Koala Habitat Assessment Tool (KHAT) (Table 4, (DoE, 2014)) for use with the data available within the nominated areas and broader Strategic Assessment Area.

The KHAT scores five attributes related to the quality and extent of Koala habitat, with each attribute scored out of 2. A total score of 10 is possible, and habitat a score of five or greater is habitat critical to the survival of the Koala. The five attributes considered in the KHAT are:

- Koala occurrence
- Vegetation composition
- Habitat connectivity
- Key existing threats
- Recovery value

A number of data sets were compiled for use in the mapping of habitat critical to the survival of the Koala within the Strategic Assessment Area. A method was then prepared based on the KHAT for use in the Strategic Assessment Area.

As a first step the habitat units to be assessed were defined by combining a compilation vegetation data set (see table below) with the mapping of Koala corridors for this project. These units were then interrogated against several different data sets (Step 2 – Step 6) to identify habitat critical to the survival of the Koala. Data sets used to define habitat critical to the survival of the Koala include Koala sighting records (OEH, 2019), Koala corridor mapping, an assessment of connectivity and key existing threats (road kill records (OEH, 2019) and adjacency to urban areas).

The method applied is described in Table 11-27.

Table 11-27: Method used to map habitat critical to the survival of the Koala within the Strategic Assessment Area

Step	KHAT attribute	Approach	Score allocated	Data used
Step 1	N/A	Habitat units were defined by combining a compilation vegetation data set (see column 5) with the mapping of Koala corridors. Koala corridors were assigned to individual habitat units by Plant Community Type (PCT) and broad vegetation condition (intact, scattered etc.) All internal line work between habitat units was dissolved where PCT, condition and corridor rank were identical. In the case of a Koala corridor not being allocated a PCT or condition state due to the land not being identified as native vegetation: Polygons smaller than 0.5 ha were removed from the habitat units layer Polygons >0.5 ha were allocated a PCT of 9999 and a condition of Unknown The habitat units were used as the based layer for the assessment	N/A	Compilation vegetation data set (100 km buffer from Cumberland subregion). Layer includes Biosis nominated area vegetation mapping, and where this isn't available a compilation of the best available data sets, including: • Remnant Vegetation of the western Cumberland subregion, 2013. VIS_ID 4207 • The Native Vegetation of the Sydney Metropolitan Area - Version 3.1 (OEH, 2016b) VIS_ID 4489 • South East Local Land Services Biometric vegetation map, 2014. VIS_ID 4211 • Southeast NSW Native Vegetation Classification and Mapping - SCIVI. VIS_ID 2230 • Koala corridor mapping
Step 2	Koala occurrence	Koala occurrence was scored based on Koala records recorded within, and adjacent to, the Strategic Assessment Area over a five year period (2016 – 2021). Distance buffers were applied to allocate appropriate scores	2 - Within 1 km of a record 1 - Within 1-2 km from a record 0 - Beyond 2 km from a record	Koala BioNet species records (EES, 2021)
Step 3	Vegetation composition	Each habitat unit was allocated a vegetation composition score. The Koala corridors mapped for the Strategic Assessment Area were used as a surrogate for this score	2 - Primary and secondary corridors 1 - Tertiary corridors 0 - Supporting habitat	Koala corridor mapping

Step	KHAT attribute	Approach	Score allocated	Data used
Step 4	Habitat connectivity	A score for habitat connectivity was calculated for each habitat unit. This was done by, first, calculating the patch size of each habitat unit. Habitat units were considered to be part of the same patch where adjacent or within 100 m of another patch Patches were then separated where intersected by a major road or rail line as these features are likely to create barriers to the movement of corridors. The roads identified for this analysis include those classified as Arterial, Motorway or Primary Road	2 - >500 ha of contiguous habitat 1 - 300-500 ha of contiguous habitat 0 - <300ha of contiguous habitat	NSW Spatial Data Services (Six Clip and Ship) (2021) – Railway and Road Segment (where road = Arterial, Motorway or Primary Road)
Step 5	Key existing threats	Key existing threats were assessed, with the lower score taken for each habitat unit Threat from road kill was determined by calculating the distance from each road kill record to each habitat unit. The threat from existing urban development was determined by calculating the distance from existing urban areas to each habitat unit	The lowest of: Threat from road kill (road kill records from 2016 - 20121). 2 - >2 km from road kill record 1 - 1-2 km from road kill record 0 - 0-1 km from road kill record Threat from urban land use (adjacency to urban land): 2 - >2 km from existing urban area 1 - 1-2 km from existing urban area 0 - 0-1 km from existing urban area	Koala BioNet species records (observation type = roadkill) (EES, 2021) NSW Spatial Data Services (SiX Clip and Ship) (2021) – General cultural area (where area = Builtup)
Step 6	Recovery value	Each habitat unit was allocated a score based on whether the habitat is likely to be important for achieving the interim recovery objectives for the species. The Koala corridors mapped for the Strategic Assessment Area were used as a surrogate for this score	2 - Primary and secondary corridors 1 - Tertiary corridors 0 - Supporting habitat	Koala corridor mapping

11.6 OTHER MATTERS OF NATIONAL ENVIRONMENTAL SIGNIFICANCE

The assessment considered all protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan and identified the following groups of protected matters as being relevant to the assessment in addition to listed threatened species and ecological communities:

- Commonwealth land
- Migratory species
- Wetlands of international importance (Ramsar wetlands)
- World and National Heritage

11.6.1 COMMONWEALTH LAND

PURPOSE

The Commonwealth land assessment considered the whole of the environment that might be affected over the life of the Plan. As required by Section 4.3 of the ToR, the assessment was undertaken to "describe and assess separately the likely impacts (if any) of actions taken under the Plan on the environment on Commonwealth land (as defined in section 528 of the EPBC Act)".

METHOD

All known areas of Commonwealth land within the Strategic Assessment Area were assessed. The location of these areas was identified with the help of DAWE and relevant NSW Government agencies. Consideration was also given to areas of Commonwealth land outside of the Strategic Assessment Area that may be affected indirectly by the classes of action.

Desktop information was used to understand the environment on Commonwealth land. Environmental values are presented in relation to soils, waterways and topography, vegetation, fauna, rare or sensitive values, heritage and information on the biodiversity landscape context of the site.

The assessment has been framed around the Commonwealth's 'Significant Impact Guidelines 1.2 – Actions on, or impacting upon, Commonwealth land and Actions by Commonwealth Agencies'.

RESULTS

A profile of the environment on each of the Commonwealth land sites is provided in Chapter 35.

11.6.2 MIGRATORY SPECIES

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan. This includes:

- Identification of key sites and habitats
- Identification of important populations

METHOD

The migratory species relevant to the assessment include:

- Nine species addressed in the *Referral guideline for 14 migratory birds listed under the EPBC Act* (migratory bird referral guidelines), released in September 2015 (DoE, 2015)
- 21 species addressed in the *Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species* (migratory shorebird referral guidelines), released in 2017 (DoEE, 2017)

The approach to understanding the values within the Strategic Assessment Area for each of these migratory species was framed around the key elements of these guidelines.

Migratory bird species

For the nine migratory bird species, the assessment drew on the concepts of important habitat and ecologically significant proportions of a population. Important habitat for each species was identified based on the PCTs that correspond to the important habitat descriptions set out in the passerine bird referral guidelines.

Ecologically significant proportions of a population of each of the species was determined using observation records from Birdlife Australia, the Atlas of Living Australia, and BioNet Atlas. The analysis used a conservative estimate of individuals based on the total recorded sightings of each species per year across the Cumberland subregion.

Migratory shorebird species

Habitat mapping was undertaken broadly in accordance with the approach outlined in the EPBC guidelines (DoEE, 2017). However, the method applied was more precautionary than required under the EPBC guidelines to ensure that no important habitat sites were missed.

The process involved the following steps:

Step 1: Analysis of records across the Cumberland subregion

Records were compiled and examined across the whole of the Cumberland subregion. The initial step considered the subregion as a single habitat unit to determine which species exceeded the thresholds for important habitat across the whole area (i.e. which species occur in numbers greater than the threshold when records in the subregion are summed).

Step 2: Identification of important migratory shorebird habitat sites

The spatial distribution of records was then assessed to identify the individual wetland and waterbody (or wetland mosaic) where the thresholds were exceeded at a site level. Each wetland that was identified as important for migratory shorebirds had its boundary marked and a 250 m buffer applied. This buffer distance is consistent with the guidelines which suggest buffer distances ranging from 165 to 255 m to mitigate against disturbance (DoEE, 2017).

For ephemeral wetlands the threshold was considered across every year where records were held.

For permanent wetlands, the guidelines suggest considering the last five years. The approach taken for this assessment was to look at records for the last 20 years (since 2000) for sites that were thought to be permanent. This acknowledges the uncertainty in determining if habitat sites are permanent or ephemeral across the Strategic Assessment Area.

Step 3: Identification of potential migratory shorebird habitat

The remaining potential migratory shorebird habitat in the subregion was determined based on the presence of suitable wetlands throughout the landscape that exceed 1.5 ha in area. This 1.5 ha threshold was used as a proxy for the minimum disturbance distance for shorebirds of 150 m.

Wetland mapping layers were interrogated from the Directory of Important Wetlands (DoEE, 2018) and the LPI topographical data Hydro Area layer (LPI, 2016) to identify areas of potential habitat.

RESULTS

The results of the migratory bird and migratory shorebird habitat assessment is provided in Chapter 32.

11.6.3 WETLANDS OF INTERNATIONAL IMPORTANCE (RAMSAR WETLANDS)

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan. This includes:

- Identification of key sites and habitats
- Condition of protected matters, including where relevant, seasonal and annual variability, and their likelihood to alter over time
- Key threatening processes

METHOD

Towra Point Nature Reserve Wetland is the only Ramsar wetland relevant to the assessment. It is located outside of the Strategic Assessment Area. Available desktop information was used to understand the environmental values at Towra Point Nature Reserve. The assessment focused on the ecological character of the wetland, which is a key concept under the Ramsar Convention and the main element for the consideration of significant impacts under the EPBC Act.

RESULTS

The description of the environmental values at Towra Point Nature Reserve is provided in Chapter 33.

11.6.4 WORLD AND NATIONAL HERITAGE

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan.

METHOD

A description of the World and National Heritage properties relevant to the assessment was developed based on available desktop information. For World Heritage, the assessment focused on the Outstanding Universal Value of the property, including an understanding of the attributes that meet the relevant listing criteria, how the property meets the conditions of integrity and the way in which the property is protected and managed.

For National Heritage, a description of each site focused on the heritage values that meet the criteria for listing.

RESULTS

A description of the World and National Heritage properties relevant to the assessment is provided in Chapter 34.

12 Approach to the impact assessment

The approach to analysing and assessing the impacts of the development under the Plan is set out in detail in each of the relevant Chapters of the Assessment Report, as follows:

- Avoiding and minimising impacts – see Chapter 14
- Addressing serious and irreversible impacts – see Chapter 25
- Assessing:
    - Direct impacts:
        - see Chapter 23 for the approach to NSW-listed matters
        - see Chapters 27-35 for the approach to Commonwealth-listed matters
    - Indirect impacts – see Chapter 15 for the approach to NSW and Commonwealth-listed matters
    - Prescribed impacts – see Chapter 24
    - Cumulative impacts – see Chapter 38
- Evaluation of the overall acceptability of the Plan – see Chapter 41

13 Data and limitations

This Chapter:

- Summarises the key types of information used in the Assessment Report
- Describes the key data sets on biodiversity values and how they were used
- Identifies the key limitations associated with:
  - Field surveys
  - Vegetation and species mapping
  - BAM credit calculations

The data and limitations associated with the preparation of specific reports that informed this Assessment Report, such as expert reports and the trend analysis, are described in these documents (see Supporting Documents C and D).

As described in Chapter 10, the technical methods for describing the EPBC protected matters impacted by the Plan were independently peer-reviewed to meet a requirement of the ToR. The peer review report (see Supporting Document B) concluded that in general:

- The data sets, methods for data collection and assumptions associated with the methods are appropriate for a large-scale strategic assessment process such as this project
- The methods used are generally conservative and are unlikely to under-represent the presence or distribution of any TEC or species (and are more likely to over-predict presence and distributions)

The peer review report recommended that further details associated with the input data and assumptions be provided in the Assessment Report to provide regulators and the public more complete understanding of limitations, including:

- Categorisation of EPBC species – further explain limitations associated with information sources used in the categorisation process, including whether they incorporate up to date information and their relevant scale
- TEC mapping method – provide further details associated with the input data, including details of the extent and dates of field validation undertaken for the source mapping
- Species Distribution Modelling – provide further details associated with the assumptions of the model to provide a more complete understanding of the factors affecting the outcomes of the model
- Assumed presence using a knowledge-based method – the exclusion of habitat based on patch size needs to be explained and justified
- Important populations – for the species that have been determined not to have important populations within the subregion and have had records excluded based on the lifespan of the species, discuss implications of this approach

These limitations are discussed in Section 13.3.

13.1 TYPES OF INFORMATION SOURCES

A wide variety of information sources and processes were used to prepare the Assessment Report, including:

- Data sets on biodiversity values
- Surveys and field verification
- Scientific literature
- Government strategies, plans, policies and guidelines
- Use of expert reports under the BAM
- Existing knowledge of ecological consultants
- Expert workshops, including technical representatives from EES
- Expert elicitation for the trend analysis (see Supporting Document D)

The information used in this Assessment Report is consistent with the requirements of the BAM and the ToR.

The data sets used across the nominated areas and broader Strategic Assessment Area represent the best available information on biodiversity and other values and were drawn from a wide variety of sources. Where land access was granted, field surveys and verification were undertaken to improve the data.

13.2 KEY DATA SETS

A large number of data sets were collated and generated for use in the Assessment Report. These are summarised in Table 13-1. The data sets cover a range of themes, including:

- Vegetation mapping
- Mapping of species distribution and habitat
- Mapping of protected lands and other conservation planning information
- Soil, geology and landscape mapping
- Mapping of topographic features such as water bodies and drainage lines

13.2.1 LIDAR DATA

LiDAR data was also used in the development of the native vegetation map and species polygons (see Attachment B, Section B.5 for further details on the LiDAR data used for species polygons).

The LiDAR metadata is as follows:

- Source: A Division of Department of Finance, Services and Innovation - PENRITH, 2kmx2km Point Cloud Metadata (https://s3-ap-southeast-2.amazonaws.com/nsw.elvis/z56/Metadata/Penrith201102-LID1-C3-AHD_2826250_56_0002_0002_Metadata.html#)
- Abstract: The coverage of this dataset is over the PENRITH region. Data of this specification (Spatial Services Category 1 LiDAR) contains point data in LAS format sourced from a LiDAR (Light Detection and Ranging) ALS50 (SN101) sensor. The processed data has been manually edited to achieve ICSM Classification Level 3 whereby the ground class contains minimal non-ground points such as vegetation, water, bridges, temporary features, jetties etc. This data has an accuracy of 0.3m (95% Confidence Interval) vertical and 0.8m (95% Confidence Interval) horizontal with a minimum point density of 1.05 points per square metre. For more information on the data accuracy, refer to the lineage provided in the data history
- Purpose: To provide fit-for-purpose elevation data for use in applications related to coastal vulnerability assessment, natural resource management (especially water and forests), transportation and urban planning
- Topic Category: location, elevation, geoscientific information
- Acquisition Start Date: 2011-02-24
- Acquisition End Date: 2011-02-24
- Spatial Accuracy Horizontal: +/-0.80@95% Confidence Interval
- Spatial Accuracy Vertical: +/-0.30 @95% Confidence Interval

Table 13-1: Sources of data used in the Assessment Report

Data set theme	Data set name	Custodian	Date	Details	Use on project
Drainage and water bodies	Directory of Important Wetlands	DAWE	2018	Data set containing boundaries for wetlands listed on the Directory of Important Wetlands	Used in determining the landscape context components of the BAM plus mapping for water dependant species
	NSW Digital Topgraphic Database - Hydro Areas Dataset	LPI	2019	Data set containing boundaries of hydrography feature types - water body areas and water courses	Used to inform the assessment of prescribed impacts for hydrology and water bodies
Land use	NSW land use polygons	EES	2013	NSW land use information including food production, forestry, nature conservation, infrastructure and urban development	Layer used in preparing native vegetation mapping for the nominated areas
Protected lands and conservation planning	Biobank sites	EES	2019	Data layer containing boundaries of Biobank sites	Layer used in determining the amount of protected land within the Plan Area
	Conservation agreements	EES	2018	Data layer containing boundaries of conservation agreements	Layer used in determining the amount of protected land within the Plan Area
	Cumberland subregion BIO Map	EES	2015	A map of core areas and corridors identified in western Sydney	Used to calculate impacts to, and protection of, important landscape features and as a surrogate for connectivity
	Metro Region biodiversity offsets	EES	2018	Data layer containing boundaries of known biodiversity offsets protected under relevant covenants governed by the relevant local Council, in the Sydney Metropolitan Region	Layer used in determining the amount of protected land within the Plan Area
	NCT Agreements	EES	2018	Data layer containing boundaries of Nature Conservation Trust Agreements	Layer used in determining the amount of protected land within the Plan Area
	NSW National Parks Estate	EES	2020	Data layer containing boundaries of National Parks, Nature Reserves and other NPWS estate	Layer used in determining the amount of protected land within the Plan Area
	Perpetual Lease Covenant	EES	2018	Data layer containing boundaries of Perpetual Lease Covenants	Layer used in determining the amount of protected land within the Plan Area

Data set theme	Data set name	Custodian	Date	Details	Use on project
	Registered Property Agreements	EES	2018	Data layer containing boundaries of Registered Property Agreements	Layer used in determining the amount of protected land within the Plan Area
Soils, geology and landscapes	NSW (Mitchell) Landscapes Version 3.1	EES	2002	Mapping of landscapes in NSW defined by landform, topography, geology, soil, climate and vegetation	Soil landscape assessment as part of the BAM assessment
	LiDAR data	New South Wales Spatial Services	2018	Layer containing LiDAR point cloud for nominated areas. LiDAR data used of varying currency, and is generally captured in 2011 across the nominated areas	Preparation of a Canopy Height Model (CHM) to assist vegetation mapping preparation within the nominated areas and identification of topographic features such as cliff lines etc.
	NSW Soil Landscapes	EES	2017	Mapping provides an inventory of soil and landscape properties and identifies major soil and landscape qualities and constraints	Soil hazard assessment as part of the BAM assessment, informed vegetation mapping
	Topographic data (Digital Topographic Database)	New South Wales Spatial Services	2019	A range of data sets which display topographic features, such as contours, drainage features and water bodies	Used for a number of project tasks including species polygons and distribution mapping, shorebird mapping and vegetation mapping
	Western Sydney Hydrogeological Landscapes	EES	2011	Spatial layer defining the areas of similar salt stores and pathways for salt mobilisation	Soil landscape assessment as part of the BAM assessment
Species sightings and habitat	BioNet (Wildlife Atlas) records of species sightings in western Sydney and surrounds – download of records provided by the Department	EES	2018, 2019, 2020 and 2021	Fauna and flora sightings records stored in the NSW BioNet database	Used for a number of project tasks including species habitat mapping, one input for species distribution models, an input into determining whether a species requires needs consideration under the EPBC Act, and an input into determining whether a species is a candidate species for the BAM assessment
	Conserving Koalas in Wollondilly and Campbelltown LGAs	EES	2019	Koala habitat and corridor mapping of the Appin, Wilton and Picton areas of Sydney	Data layer used to inform updated koala corridor mapping within the nominated areas. Layer accepted without modification outside nominated areas

Data set theme	Data set name	Custodian	Date	Details	Use on project
	New Atlas of Australian Birds	BirdLife Australia	1998-2015	Bird sightings database administered by BirdLife Australia	Used in the preparation of species polygons for bird species
Vegetation mapping	Remnant Vegetation of the western Cumberland subregion, 2013 Update. VIS_ID 4207	EES	2013	Vegetation data layer covering western Sydney. Update of the Remnant Vegetation Mapping of the Cumberland Plain (OEH, 2013b). Contains details on Plant Community Type (PCT), map unit and dated condition information	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species polygons outside the nominated areas
	South East Local Land Services Biometric vegetation map, 2014. VIS_ID 4211	EES	2015	A seamless standardised vegetation map, from a combination of existing available data, which covers the full extent of the South East Local Land Services (SE LLS) region. Compiled from best available data sets in the region. Contains information on PCTs and map units	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species polygons outside the nominated areas
	Southeast NSW Native Vegetation Classification and Mapping - SCIVI. VIS_ID 2230	EES	2010	Classification, descriptions and mapping of native vegetation types of southeast NSW (including the South Coast and parts of the eastern tablelands)	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species polygons outside the nominated areas
	The Native Vegetation of the Sydney Metropolitan Area - Version 3.1 VIS_ID 4489	EES	2016	Vegetation data layer covering the Sydney metropolitan area. Extends west to cover all of Georges and Parramatta River catchments. Contains details on PCT, map unit, TEC, and disturbance	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species polygons outside the nominated areas

13.3 LIMITATIONS

There are a number of limitations associated with the collection and use of data in this Assessment Report.

The limitations can be categorised into three main themes:

- Field survey limitations (i.e. land access, project scale, data and drought)
- Vegetation and species mapping limitations
- BAM credit calculation limitations

13.3.1 FIELD SURVEYS

Table 13-2 identifies limitations with field surveys and provides comment on the implications of these limitations or any precautionary measures that were taken to address these.

Table 13-2: Limitations of field surveys

Limitation	Comment
BAM native vegetation plots and threatened species surveys were only undertaken within the nominated areas, and were not undertaken within the transport corridors outside the nominated areas	While the best available data was used to assess impacts of the transport corridors outside the nominated areas, the assessment may be less accurate as it is based on existing data that has not been recently confirmed
Within the nominated areas, BAM native vegetation plots and threatened species surveys were restricted to sites where access was granted by landholders. While the number and distribution of BAM plots met BAM requirements, limited land access meant surveys were not possible across the entire urban capable land	The Department undertook an extensive program to seek approval from landholders for land access, involving: • Letter mailouts to landholders in the nominated areas • Follow-up emails or phone calls to public landholders and businesses such as developers where phone numbers were publicly available • Door knocking (Biosis) in high priority areas for surveys where no responses were received
Targeted species surveys were not always undertaken strictly in accordance with EES survey guidelines due to the very large scale of the Plan Area	Species were assumed to be present based on potential habitat maps created using a knowledge-based method, refined by ground validation species or habitat presence/absence surveys. See further justification related to surveys in Section 11.5.2
For some BAM plots, some BAM data components were based on existing BBAM plot data	In these cases, sites were re-visited and the additional BAM data components were captured to ensure the plot data was consistent with BAM
The survey period was exceptionally dry. Significant rainfall deficiencies occurred across eastern Australia and the eighth-lowest January to November rainfall since 1900 was recorded for NSW for 2018 Rainfall was in the lowest 10 per cent of all years for Western Sydney. NSW had its warmest January–November period on record for 2018, compounding the impact of low rainfall (BOM, 2019)	These conditions are likely to have affected the results of the field surveys – likely reducing vegetation integrity scores and the ability to detect some flora species

13.3.2 MAPPING AND OTHER METHODS

Table 13-3 identifies limitations with vegetation and species mapping and provides comment on the implications of these limitations or any precautionary measures that were taken to address these.

Table 13-3: Limitations of mapping and other methods

Limitation	Comment
The criteria used to categorise EPBC matters needing assessment was applied based largely on existing data	There may be limitations associated with the quality and accuracy of the existing data, such as DAWE's species distribution maps. However, the best available information was used in applying the criteria The criteria used to categorise EPBC matters is generally objective and does not involve subjective judgement. Where applying the criteria involved judgement (criteria 3), expert ecologists from Biosis were used
Mapping - general Native vegetation, TEC and species polygons were prepared based largely on existing data	The final outputs from the mapping and modelling will be limited by the input data. Poor quality (i.e. inaccurate species data, soil mapping or vegetation mapping) or missing data may result in the identification of conservation priorities or potential development impacts that do not align with the on-ground environment
On-ground validation of native vegetation, TEC and species mapping was only undertaken within the nominated areas where land access was granted. No validation of mapping was undertaken within the transport corridors outside the nominated areas	While the best available data was used to assess impacts of the transport corridors outside the nominated areas, the assessment may be less accurate as it is based on existing data that has not been recently confirmed
Assumptions were made about PCT types and condition for areas not surveyed. The type of PCT was assumed to be correct where native vegetation extent aligns with PCTs as mapped by EES (2013, 2016),soil/landscape mapping aligned with the PCT description, and assessment of all other datasets and aerial imagery did not provide a more likely alternative	At suitable vantage points in public areas, ecologists confirmed continuity of vegetation communities, assessed broad condition state and level of habitat degradation and verified existing vegetation mapping where access was unavailable
The vegetation mapping within the 1500 m buffer for the assessment under the BAM was undertaken using existing vegetation mapping only and therefore the native vegetation extent for derived grasslands is likely to be under-represented	
TEC mapping TEC mapping is based on the native vegetation mapping and is subject to the same limitations (discussed above) Due to data limitations, some assumptions were made to establish the rule-sets used to map Commonwealth and NSW listed TECs	Details of the rule-sets used to map EPBC TECs and the field validation undertaken for the TEC mapping within the nominated areas are provided in Chapter 11 The peer review concluded that the TEC mapping method used is generally conservative and is more likely to over-predict distribution of TECs
Post-submissions mapping updates Following submissions received from BAM Accredited Assessors, PCT mapping was updated in a number of locations across the nominated areas. This has resulted in both changes to vegetation type and condition, as well as extent (including polygon geometry)	Updates to PCT mapping has resulted in changes to dependent datasets including TECs and species polygons. Were updates were required to species polygons developed by species exerts, these changes were discusses with the experts and broadly accepted
Species polygons (mapping) Some candidate SCS were considered to be too cryptic for detection or difficult to map and model	These species were assigned to recognised experts for assessment (BAM expert reports)
Species polygons - Assumed presence using a knowledge-based method	The habitat parameter rule-sets used to map species were based on the best available information sourced

Limitation	Comment
Only potential habitat for species was able to be mapped due to the very large scale of the Plan Area. The species polygons are therefore likely to be precautionary and greatly overpredict actual habitat Due to data limitations, some assumptions were made to establish the habitat parameter rule-sets used to map species habitat For species with known patch size thresholds identified in scientific literature, the rule-set included exclusion of small patches of native vegetation from the species map to provide a more accurate prediction of potential habitat	from SPRAT and BioNet profiles, NSW Threatened Biodiversity Data Collection, conservation advices, recovery plans and scientific literature. Where judgement was needed to make a decision, expert ecologists from Biosis were used Details of the habitat parameter rule-sets used to prepare species polygons and the field validation undertaken for the this mapping within the nominated areas are provided in Chapter 11 The peer review concluded that this species polygons method used is generally conservative and is more likely to overpredict species habitat
Epacris purpurascens var. *purpurascens* impacts have been calculated based on assumed presence using a knowledge-based method to determine the area of potential habitat present for the species within the nominated areas. Impacts to this species are required to be presented as an impact to stems/individuals (a 'count' species) in accordance with the BAM. As generating a count of impacted stems/individuals is not possible using the KMB, an estimate of stems/individuals impacted was made based on existing BioNet data	The estimated impact to *Epacris purpurascens* var. *purpurascens* stems/individuals is based on all existing records for the species within 20 kms of the modelled habitat, and is considered to be a conservative overestimate of the level of actual impact to the species Details of the method used to estimate impacts is provided in Chapter 26
Species polygons – Species Distribution Modelling All data used for species distribution models was based on presence-only data, meaning it is data without any 'absence' records of species (i.e. where observers have not noted the absence of a species at surveyed sites)	Undertaking SDM modelling with presence-only data results in relative measures of habitat suitability. A location with a predicted high habitat suitability score is only high relative to other locations in the Plan Area, and not necessarily high-quality habitat in absolute terms
The study area for the SDM modelling was limited to a 10 km buffer around the Cumberland subregion. For some species, this comprises only a small part of their range, which may reduce the accuracy of the modelling	
SDM modelling does not account for factors such as historical accidents and competition with other species that may significantly drive species distributions	
SDM modelling may overpredict actual habitat in highly-modified landscapes such as the Cumberland subregion due to the standard assumptions regarding a species occupying its niche not applying in such landscapes	
There may be large amounts of bias in the species records	Species data used in the SDM modelling was cleaned (likely inaccurate records removed) and multiple bias layers were used in the modelling to address this bias
For some of the species, there may be false associations between records and PCTs due to spatial errors in the point locations and and/or the PCT maps	
Important populations The criteria used to identify important populations was applied based largely on existing data Due to data limitations, some assumptions were made in applying the criteria to identify important populations.	There may be limitations associated with the quality and accuracy of the existing data, such as information on species' Area of Occurrence. However, the best available information was used in applying the criteria Information was sourced from SPRAT/BioNet profiles,

Limitation	Comment
For some species, this included excluding records that were older than the lifespan of the species in some cases	Threatened Biodiversity Data Collection, conservation advices, recovery plans and scientific literature Where applying the criteria involved judgement (particularly criteria 7 and 9), expert ecologists from Biosis were used to inform decisions Excluding old records based on the lifespan of the species was undertaken for five fauna species. This was only done where few records existed and there were no recent records in the Cumberland subregion
Shorebird mapping Where count data has not been provided with a BioNet or Birds Australia record, each point has been assumed to represent one individual within the shorebird mapping	

13.3.3 BAM CREDIT CALCULATIONS

Table 13-4 identifies limitations with the BAM credit calculations and provides comment on the implications of these limitations or any precautionary measures that were taken to address these.

Table 13-4: Limitations of BAM credit calculations

Limitation	Comment
Some plot data collected in vegetation mapped as NOG has returned a Vegetation Integrity (VI) of >15 (the cut-off score for the requirement to offset endangered or critically endangered TECs)	This has occurred across a low proportion of the plots and is largely explained through either a high cover of a single native grass species in the ground layer (most often Common Couch *Cynodon dactylon*) or a high cover of "litter" as defined under the BAM (most often a result of dead and/or detached grass on the ground as a result of the unusually dry survey seasons)Furthermore, the majority of the BAM plot data shows the areas sampled to be of very low ecological condition All NOG vegetation zones were found to have a VI score of <15 when all collected plots are considered, as is required by the BAM
Where impacts to SCS were less than 0.005 ha (i.e. 0.00 when rounded to 2 decimal places), the impact was completely discounted and not entered into the BAM calculator	Such impacts typically relate to 'slivers' of slight mismatch between various spatial layers used to prepare the impact assessments
Impacts to candidate SCS were generally either allocated to a vegetation zone or NOG polygon for entry into the credit calculator. Where the habitat for the threatened species fell outside of these areas the impact was not entered into the BAM calculator and was identified as a prescribed impact

VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 3 Attachment Contents

Part 3 Attachment List of Tables

A. Justification for removal of species credit species

This Attachment provides the justification for the removal of species credit species (SCS) from further assessment. Table A-1:

- Provides the full list of species identified using the BAM credit calculator in accordance with Step 1, Section 6.4 of the BAM
- Identifies the nominated areas in which the species is further assessed
- If relevant, justifies the removal of the species for needing further assessment in one or more of the nominated areas

As outlined in Section 11.1.1 of Chapter 11, relevant NSW-listed species were identified by application of the following three step process:

- Step A: Identification of an initial list of species (Step 1, Section 6.4 of the BAM)
- Step B: Initial exclusion of SCS (Steps 2 and 3, Section 6.4 of the BAM)
- Step C: Consideration of best available ecological data as provided by Section 6.1.1.2 of the BAM. This step involved:
    - Consideration of:
        - Best available ecological data
        - The Threatened Biodiversity Data Collection
        - Species records in BioNet
        - Published peer reviewed literature
    - Followed by application of the following factors for excluding SCS:
        - Geographic extent of a species occurring outside one or more of the nominated areas, or urban capable land
        - Lack of suitable habitat within one of more of the nominated areas or urban capable land
        - Lack of records in one or more of the nominated areas over the past 55 or more years (up to >200 years)

Please refer to Section 11.1.1 of Chapter 11 for a detailed discussion of the method and approach.

Given the complexity of information relating to Koala, a detailed standalone section is provided in Section A.2 (after Table A-1) that sets out the justification for excluding the species from GPEC and WSA.

A.1 JUSTIFICATION FOR REMOVAL OF SCS

Table A-1: Justification for removal of species credit species from requiring further assessment

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Acacia bynoeana	Bynoe's Wattle	✓	✓	✓	✓	Yes	*Acacia bynoeana* is a shrub that occurs in central eastern NSW, from the Hunter District (Morisset) south to the Southern Highlands and west to the Blue Mountains. Habitat comprises heath or dry sclerophyll forest on sandy soils. It prefers open, sometimes slightly disturbed sites. Records occur in about 30 locations within the distribution of the species (OEH, 2019i). The closest records to the nominated areas occur immediately to the North East of Glenfield on sandy soils, outside the nominated areas The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.	Yes	No	N/A
Acacia gordonii	Gordon's wattle	R	X	X	X	No	*Acacia gordonii* is a shrub that is restricted to the north-west of Sydney. It has a disjunct distribution in the lower Blue Mountains and the Maroota/Glenorie area. Habitat comprises dry sclerophyll forest and heathlands amongst or within rock platforms on sandstone outcrops. Records occur in only a few	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							locations in the lower Blue Mountains and Maroota/Glenorie area (OEH, 2019a). The species was removed as a candidate species in Wilton because: • Urban capable land is outside the geographic extent of the species • Associated PCTs do not occur within urban capable land			
Acacia prominens - endangered population	Gosford Wattle	R	X	R	R	No	*Acacia prominens* is a tree. The endangered population occurs outside the nominated areas in the Kogarah – Hurstville local government areas. This occurrence is disjunct from other occurrences of the population of the species and at the southern limit of the species range (NSW Scientific Committee, 1998a). The population was removed as a candidate species in Wilton, WSA, and GPEC due to the listed extent occurring outside urban capable land.	No	No	N/A
Acacia pubescens	Downy Wattle	✓	✓	✓	✓	Yes	*Acacia pubescens* is a shrub that occurs around the Bankstown-Fairfield-Rookwood area and the Pitt Town area, with outliers occurring at Barden Ridge, Oakdale, and Mountain Lagoon. Habitat comprises gravely soils, often with ironstone, within open woodland and forest in a variety of vegetation communities, including Cooks River/Castlereagh Ironbark Forest, Shale/Gravel Transition Forest and Cumberland Plain Woodland	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							(OEH, 2019l). There are recent records of this species outside the nominated areas, and the species has the potential to occur within WSA. The other nominated areas contain mostly old records (from 1910 and 1960) with low spatial accuracy in areas that are now highly urbanised. This species is easily recognisable so is unlikely to be missed during surveys. The species was retained as a candidate species in all nominated areas due to suitable habitat that has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.			
Allocasuarina glareicola		X	X	R	✓	Yes	*Allocasuarina glareicola* is a shrub largely found in the vicinity of Castlereagh and Londonderry within an area of 27 km^2 (Fairley, 2004). An outlier population occurs on Commonwealth land at the Holsworthy Military Area, south-west of Sydney (French, Pellow et al., 2001). Habitat comprises open Castlereagh woodland, growing on tertiary alluvial gravels, with yellow clayey subsoil and lateritic soil (DEWHA, 2008a). Preferred soils for the species are found in GPEC around the Penrith Lakes area.	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							The species was retained as a candidate species in GPEC because suitable habitat has the potential to occur in urban capable land. The species was removed in WSA because of a lack of records and a lack of suitable habitat within urban capable land.			
*Anthochaera phrygia**	Regent Honeyeater	R	R	R	R	No	*Anthochaera phrygia* is a medium sized bird mainly confined to its two main breeding areas in NSW (at Capertee Valley and the Bundarra-Barraba region) and surrounding fragmented woodlands. Minor and sporadic breeding occurs in other areas such as Warrumbungle National Park, Pilliga forests, Mudgee-Wollar region, and the Hunter and Clarence Valleys (NSW Scientific Committee, 2010). Habitat comprises dry open forest and woodland, particularly Box-Ironbark woodland, and riparian forests of River Sheoak. Until very recently, all records in the Cumberland subregion related to foraging birds. However, at the end of 2019 a pair was observed successfully breeding near Mulgoa at Fernhill Estate, just west of the boundary between the WSA and GPEC. The nest was recorded in vegetation mapped as Shale Sandstone Transition Forest. It is connected to the much broader areas of intact vegetation west of the Strategic Assessment Area; although the nest site itself is	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							towards the interface of this vegetation and cleared rural land. The site is protected and managed in perpetuity under a biobanking agreement. The species was removed as a candidate species from all nominated areas because EES confirmed mapped important habitat for the species does not occur within urban capable lands.			
Burhinus grallarius	Bush Stone-curlew	R	R	R	R	No	*Burhinus grallarius* is a large bird that occurs throughout much of Australia, although in the south-east it is rare or extinct throughout its former range. Habitat comprises open woodlands with few shrubs, and short, sparse grasses of less than 15 cm, with scattered fallen timber, leaf litter and bare ground present (NSW DEC, 2006). Habitat is associated with broad ground and understorey structural features and is not necessarily associated with any particular vegetation communities. Removal of fallen timber affects the suitability of habitat as this comprises foraging habitat and the species relies on it for camouflage when roosting (NSW DEC, 2006). Records occur across the Cumberland subregion, but there are few recent records and no records within WSA or Wilton. Records only occur within GPEC and GMAC, a total of four within GPEC, and five within GMAC. GPEC records are prior to 1996 from within the RAAF base at Orchard Hills. As no new BioNet records of the	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							species exist in that location for over the last 23 years, more than a generation's length for this species, the birds are considered no longer to be present, based on lack of sightings/records. The remaining records from GPEC are specimen records form the Australian Museum, dated as 1884 and 1895. GMAC records are prior to 1981, with a very low level of accuracy (10,000m), with limited location descriptions. Records from 1981 are noted as 'Appin', with the remainder being specimen records form the Australian Museum, dated as 1860/1861. A single record occurs from within the Cumberland subregion since 1996, noted as being from 2012 in Greystanes and associated with WIRES. No more information is provided in BioNet. Due to the isolated nature of this record, both temporally and spatially, it is considered a vagrant record, and not evidence of the species persistence in the subregion. The species was removed as a candidate species in all nominated areas because suitable micro-habitats have undergone a long history of degradation and are now considered scarce in urban capable land, and the substantial lack of recent records within the subregion. Considerable survey effort has been undertaken for the species across the Cumberland subregion since 1996			

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							and if present, it is considered likely that the species would have been positively recorded in that time.			
Caladenia tessellata	Thick Lip Spider Orchid	R	R	R	R	No	*Caladenia tessellata* is an orchid that is known within NSW from two disjunct areas; one population near Braidwood on the Southern Tablelands and three populations in the Wyong area on the Central Coast (NSW Scientific Committee, 2002). Habitat comprises grassy sclerophyll woodland in clay loam or quartz-rich sandier soil (OEH, 2019ak). The total population size is estimated to be less than 50 individuals. Old records occur in the Penshurst (recorded 1901) and Como (recorded 1930) areas. The species was removed as a candidate species in all nominated areas because of a lack of records and suitable habitat within urban capable lands.	No	No	N/A
*Calidris ferruginea**	Curlew sandpiper	X	X	R	X	No	*Calidris ferruginea* is a small bird that breeds in Siberia and migrates to Australia (as well as Africa and Asia) for the non-breeding period (NSW Scientific Committee, 2011). In NSW, the species occurs along the coast, particularly in the Hunter Estuary, and sometimes in freshwater wetlands in the Murray-Darling Basin. Foraging habitat in NSW mainly comprises intertidal mudflats. The species was removed as a candidate species in WSA because:	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• Of a lack of suitable habitat within urban capable land • Important mapped areas do not occur within the nominated areas			
Callistemon linearifolius	Netted Bottle Brush	R	R	R	R	No	*Callistemon linearifolius* is a shrub that occurs from the Georges River to Hawkesbury River in the Sydney area, and north to the Nelson Bay area of NSW. Habitat comprises dry sclerophyll forest. For the Sydney area, recent records are limited to the Hornsby Plateau area near the Hawkesbury River. There are currently only five or six known populations of the species remaining in the Sydney area, of the 22 populations recorded in the past. Three of these are reserved in Ku-ring-gai Chase National Park, Lion Island Nature Reserve, and Spectacle Island Nature Reserve. Further north it has been recorded from Yengo National Park (NSW Scientific Committee, 1999a). The species was removed as a candidate species in all nominated areas because urban capable lands are outside the geographic extent of the species.	No	No	N/A
*Callocephalon fimbriatum**	Gang-gang cockatoo	✓	✓	R	✓	Yes	*Callocephalon fimbriatum* is a bird restricted to the south-eastern coast and highlands, from the lower Hunter and northern Blue Mountains to the Southwestern Slopes, south to and contiguous with the Victorian population. Habitat comprises eucalypt open forests	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							and woodlands with an acacia understorey (NSW Scientific Committee, 2008a, 2018). Breeding habitat includes remnant tall moist forest. Nests are located in hollows that are 10 cm in diameter or larger and at least 9 m above the ground in eucalypts (DPIE, 2020b). The species has been recorded within the vicinity of the nominated areas nesting in tall eucalypts within sandstone gullies (e.g. The Oaks area). The species was retained as a candidate species in Wilton, GMAC and GPEC because records occur in the vicinity of urban capable lands. The species was removed in WSA because: • Breeding microhabitats are considered substantially degraded within the WSA nominated area • It has never been recorded in the WSA nominated area (based on BioNet as-held data export) Targeted surveys during breeding season and habitat assessment surveys have been undertaken across the nominated areas for this species. The species was not recorded, however potential breeding habitat was found to be present.			
*Calyptorhynchus lathami**	Glossy black cockatoo	✓	✓	R	✓	Yes	*Calyptorhynchus lathami* is a bird that occurs mainly in the eastern part of NSW from the coast to the tablelands, with populations on the western slopes and	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							plains tenuously connected to those on the tablelands. Habitat comprises eucalypt open forest and woodland with hollow-bearing trees and a midstory of sheoaks. It nests in tree hollows, and forages exclusively in sheoak species (NSW Scientific Committee, 2008b). Favoured habitat occurs on richer soils and within gentle terrain, and where *Allocasuarina* species are present. Records occur in the vicinity of the nominated areas, mainly where there is better tree cover and *Allocasuarina* species. Hollow-bearing trees within these areas are potential breeding habitat. The species was retained as a candidate species in Wilton, GMAC and GPEC because records occur in the vicinity of urban capable lands. The species was removed in WSA because: • Breeding microhabitats are considered substantially degraded within the WSA nominated area • It has never been recorded in the WSA nominated area (based on BioNet as-held data export) Targeted surveys during breeding season and habitat assessment surveys have been undertaken across the nominated areas for this species. The species was not recorded, however potential breeding habitat was found to be present.			

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Cercartetus nanus	Eastern Pygmy-possum	✓	✓	✓	✓	Yes	*Cercartetus nanus* is a small marsupial that in NSW occurs from the coast inland as far as the Pilliga, Dubbo, Parkes, and Wagga Wagga on the western slopes. The species occurs within a broad range of habitats from rainforest through to sclerophyll forest (including Box-Ironbark) and woodland to heath (OEH, 2019n), generally in more intact forms of vegetation. Records occur to the south-east of Wilton and are all in intact vegetation on a different substrate generally to that of urban capable lands (sandstone rather than shale). Most records within the Cumberland subregion are either inaccurately located or are located in the Bargo River and not within urban capable lands. The record near Campbelltown is located to the north-east and is outside the Cumberland subregion. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands. Targeted habitat assessment surveys have been undertaken across the Growth Ares for this species and potential habitat was found to be present.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Chalinolobus dwyeri	Large-eared Pied Bat	✓	✓	R	✓	Yes	*Chalinolobus dwyeri* is a small to medium sized bat that is found from Rockhampton in Queensland south to Bungonia in the NSW Southern Highlands. Habitat comprises areas with extensive cliffs and caves (OEH, 2019t). Potential habitat for the species within the nominated areas is likely to occur only in areas outside urban capable lands. The species was retained as a candidate species in Wilton, GMAC and GPEC because foraging habitat within 2 km of sandstone cliffs and caves (potential roosting/breeding habitat) occurs within the nominated areas. The species was removed as a candidate in WSA as no potential roosting / breeding habitat occurs within 2 km of the nominated areas.	Yes	No	N/A
Cynanchum elegans	White-flowered Wax Plant	R	R	R	R	No	*Cynanchum elegans* is a climbing vine that is restricted to eastern NSW and is found from Brunswick Heads in the north to Gerroa in the South. Habitat usually occurs on the edge of dry rainforest vegetation (OEH, 2019am). Within the nominated areas, the species is most likely to occur along streamlines and steeper shale lands. No records of the species occur in the nominated areas.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							The species was removed as a candidate species in all nominated areas because: • Microhabitats are considered substantially degraded within the nominated areas • It has never been recorded in the nominated areas (based on BioNet as-held data export) The urban capable lands are generally avoiding streamlines and steeper shale lands containing native vegetation where this species is most likely to occur. No dry rainforest vegetation occurs within urban capable land.			
Darwinia biflora		R	X	X	X	No	*Darwinia biflora* is an erect spreading shrub that is restricted to NSW and found in Ku-ring-gai, Hornsby, Baulkham Hills, and Ryde Local Government Area (OEH, 2017b). This species occurs on the edges of weathered shale-capped ridges and the transition area with Hawkesbury Sandstone. Most sites occur on the Lucas Heights Soil Landscape and the transition with Gymea or the Hawkesbury Soil Landscapes (NPWS, 2003). These habitat characteristics tend to occur in the lower-slope areas where the Shale Sandstone Transition Forest intersects with the sandstone enriched gully forests (PCT 1081, PCT 1181). The species may also occur in coastal upland swamp communities, but these do not occur within the nominated areas.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							The species has been removed as a candidate species in Wilton because: • Urban capable land is outside the geographic extent of the species • Associated PCTs do not occur within urban capable land			
Darwinia peduncularis		R	X	X	X	No	*Darwinia peduncularis* is a broad spreading shrub that has been recorded from Brooklyn, Berowra, Galston Gorge, Hornsby, Bargo River, Glen Davis, Mount Boonbourwa and Kings Tableland in NSW. The species occurs as local disjunct populations in coastal NSW with isolated populations in the Blue Mountains. Populations also occur within the Marramarra National Park, Wollemi National Park, Blue Mountains National Park and Berowra Valley Regional Park (NSW Scientific Committee, 1999b). Habitat comprises sandstone soils on either ridge crests or upper slopes and dry sclerophyll forest on sandstone hillsides and ridges. Potential habitat for the species within the nominated areas is likely to occur only in areas outside urban capable lands. The species has been removed as a candidate species in Wilton because: • Urban capable land is outside the geographic extent of the species	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• Associated PCTs do not occur within urban capable land			
Deyeuxia appressa		R	X	R	X	No	*Deyeuxia appressa* an erect perennial grass that is a highly restricted in NSW. Habitat comprises wet ground in the Hornsby area (Royal Botanic Gardens & Domain Trust, 2019). The species is primarily found east of the Plan Area with records from Salt Pan Creek and Killara, and questionable records from Kellyville. The species is considered to be extinct in the wild as the areas confirmed to be formerly occupied are now well developed and the species has not been otherwise reliably recorded since 1942. The species favours wetter areas that will be excluded from urban capable land as major streams will be avoided. It is not known from the Wianamatta (South Creek) area in GPEC that may be potentially impacted by transport corridors. The species has been removed as a candidate species in WSA and Wilton because: • Microhabitats considered absent from urban capable lands • The species is considered extinct within the geographic extent of the nominated areas	No	No	N/A
Dillwynia tenuifolia		R	R	✓	✓	Yes	*Dillwynia tenuifolia* is a low spreading shrub that primarily occurs in the Cumberland Plain from Windsor and Penrith in the north to Dean Park and	Yes	Yes	WSA, GPEC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							near Colebee in the east. Habitat comprises scrubby and dry heath areas that occur in Castlereagh Ironbark Forest and Shale Gravel Transition Forest. It can also be found in the transition areas between these communities and Castlereagh Scribbly Gum Woodland. Outside of its primary distribution, the species has been recorded from Voyager Point and Kemps Creek, Luddenham, and South Maroota (OEH, 2017c). The species is likely to occur in all areas of PCT 724 and most areas of PCT 725. The species was retained as a candidate species in WSA and GPEC because suitable habitat is likely to occur in urban capable lands. The species was removed in GMAC and Wilton because the nominated areas occur outside species' known geographic extent. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.			

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Dillwynia tenuifolia - endangered population		X	X	R	X	No	*Dillwynia tenuifolia* is a low spreading shrub. The endangered population occurs at Kemps Creek south of WSA (the population occurs within the existing South West Sydney Growth Area) (NSW Scientific Committee, 1997). The population was removed as a candidate species in WSA because it does not occur within urban capable land.	No	Yes	WSA
Epacris purpurascens var. purpurascens		✓	✓	R	R	Yes	*Epacris purpurascens* var. *purpurascens* is a shrub that is found in NSW from Gosford in the north, Narrabeen in the east, Silverdale in the west, and Avon Dam in the south (OEH, 2017d). Habitat comprises areas in the vicinity of creeks and swamps on sandstone in dry sclerophyll forest and scrub (NSW Scientific Committee, 1997). Surveys have been undertaken for this species within urban capable lands. The species was not recorded during surveys. Though common in the Bingara Gorge and St Marys Towers areas, the species appears to be absent from other areas. This includes adjacent properties that were assessed. The species was retained as a candidate species in Wilton and GMAC because suitable habitat is likely to occur in urban capable lands. The species was removed in WSA and GPEC because:	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• The WSA and GPEC nominated areas occur outside species' known geographic extent • Species' microhabitats are considered absent from urban capable lands within WSA and GPEC nominated areas			
Eucalyptus benthamii	Camden White Gum	✓	✓	R	R	Yes	*Eucalyptus benthamii* is a tree that is restricted to the alluvial flats of the Nepean River and its tributaries (DoE, 2014; OEH, 2017a). Habitat comprises wet forest on sandy alluvial soils along valley floors (Royal Botanic Gardens & Domain Trust, 2019). The distribution of the species includes Wilton and GMAC and south of GPEC and WSA, including west of WSA in the Bents Basin/Wallacia area. The species was retained as a candidate species in Wilton and GMAC because suitable habitat may occur in urban capable lands, although habitat is most likely to occur only in areas outside urban capable lands. The species was removed in WSA and GPEC because • Species' microhabitats are considered absent from urban capable lands within WSA and GPEC nominated areas • The species has never been recorded in the WSA or GPEC nominated areas (based on BioNet as-held data export) of a lack of records within urban capable lands.	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Eucalyptus sp. Cattai		R	X	X	X	No	*Eucalyptus sp. Cattai* is a small tree that occurs between Colo Heights and Castle Hill. It is generally found outside the subregion and considered restricted to the Cattai - Glenhaven region. Historic records occur near the Royal Botanic Gardens, Sydney (NSW Scientific Committee, 1998b). Habitat comprises scrub, heath, and low woodland on sandy soils generally in flat areas and on ridge tops (OEH, 2018d). This species was removed as a candidate species in Wilton because: • The nominated areas occur outside species' known geographic extent • Associated PCTs do not occur within urban capable land	No	No	N/A
Grammitis stenophylla	Narrow-leaf Finger Fern	R	X	X	X	No	*Grammitis stenophylla* is a small fern that occurs in eastern Queensland and NSW as far west as Narrabri. Habitat comprises moist places in rainforest and moist eucalypt forests near streams on rocks or in trees (OEH, 2018k). A single record occurs in the Cumberland subregion at Parramatta. The location of the record is close to the subregion boundary (but occurs in much wetter habitats than occur in the nominated areas). This record is old, and its location is unreliable (Royal Botanic Gardens & Domain Trust, 2019).	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							This species was removed as a candidate species in Wilton because: • Urban capable land occurs outside the geographic extent of the species • Associated PCTs do not occur within urban capable land			
Grevillea juniperina subsp. *juniperina*	Juniper-leaved Grevillea	R	R	✓	✓	Yes	*Grevillea juniperina* subsp. *juniperina* is a shrub endemic to Western Sydney. It has a restricted range, occurring on red sandy to clay soils on Wianamatta Shale and Tertiary alluvium in Cumberland Plain Woodland and Castlereagh Woodland (NSW Scientific Committee, 2000). The species is likely to occur within WSA and GPEC. The species was retained as a candidate species in WSA and GPEC because suitable habitat is likely to occur in urban capable lands. The species was removed in Wilton and GMAC because the expert report confirmed a lack of suitable habitat within urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.	Yes	Yes	GPEC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Grevillea parviflora subsp. *parviflora*	Small-flower Grevillea	✓	✓	✓	✓	Yes	*Grevillea parviflora* subsp. *parviflora* is a shrub that has a sporadic distribution throughout the Sydney Basin IBRA region (OEH, 2018e). Habitat comprises damper sandy or light clay soils, often with lateritic ironstone gravels and nodules, in a range of vegetation types from heath and shrubby woodland to open forest (OEH, 2018e). The species has been recorded during surveys undertaken for this project The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within inaccessible parts of urban capable lands.	Yes	No	Wilton
Grevillea parviflora subsp. *supplicans*		R	R	X	R	No	*Grevillea parviflora* subsp. *supplicans* is a shrub with a highly restricted distribution confined to approximately 8 x 10 km to the north-west of Sydney in the area near Arcadia and Maroota-Marramarra Creek. Habitat comprises heathy woodland associations on skeletal sandy soils over massive sandstones (OEH, 2017e). Most records occur in the Yengo and Pittwater subregions. The species was removed as a candidate species:	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• In Wilton and Greater Macarthur nominated areas because they occur outside the species' TBDC listed 'Geographic constraints' • In GPEC because associated PCTs do not occur within urban capable land			
Gyrostemon thesioides		R	R	R	R	No	*Gyrostemon thesioides* is a shrub with a highly restricted distribution in NSW. Habitat comprises hillsides and riverbanks in riparian zones on sandy soils. It has only been recorded at three sites near the Colo, Georges, and Nepean Rivers (OEH, 2018g). Existing records are poorly geolocated, but all records of the species are located in riparian corridors of high order streams. As such all habitats have been avoided within urban capable lands in the Wilton, GMAC and WSA. No records of the species occur within the GPEC, and the closest records, more recent than 1967, are over 30kms away in the Wollemi and Blue Mountains NPs. Potential habitat for the species (riparian corridors) within the nominated areas is likely to occur only in areas outside urban capable lands This species was removed as a candidate species in all nominated areas because: • Microhabitats are considered absent from urban capable lands	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• The species has not been recorded within the geographic extent of the nominated areas since 1967 along the Georges River			
*Haliaeetus leucogaster**	White-bellied Sea-Eagle	✓	✓	✓	✓	Yes	*Haliaeetus leucogaster* is a large bird that is widespread along the east coast of NSW and occurs along all major inland rivers and waterways. The species forages over large areas of open water, including swamps, lakes, larger rivers, and the sea. It breeds in tall, open forest and woodland, and swamp sclerophyll forest close to foraging areas. Nest trees typically comprise the tallest trees, often with emergent dead branches or large dead trees nearby which are used as 'guard roosts' (OEH, 2019al). The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. Targeted surveys for breeding habitat were undertaken within the nominated areas and potential habitat was recorded.	Yes	Yes	GMAC, WSA, Wilton
Haloragis exalata subsp. *exalata*	Square Raspwort	X	X	R	X	No	*Haloragis exalata* subsp. *exalata* is a shrub that occurs in four scattered localities in eastern NSW within the Central Coast, South Coast and North Western Slopes regions. Habitat comprises wet and shaded parts of riparian corridors (Miles & Cameron, 2007). It is not known the Cumberland subregion. Populations	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							recorded historically from Western Sydney are thought to no longer exist (NSW Scientific Committee, 2009b). The closest records occur at Marramarra Creek and in the Kiama area. Surveys have not been undertaken for this species within urban capable lands. The species was removed as a candidate species in WSA as urban capable land occurs outside the geographic extent of the species. Wet riparian habitats have been excluded from urban capable lands through stream buffers, and as such microhabitats for the species are considered absent from urban capable lands.			
Haloragodendron lucasii		R	X	X	X	No	*Haloragodendron lucasii* is a shrub found in a very narrow distribution spanning a 10 km range in the northern suburbs of Sydney (OEH, 2019p). Habitat comprises moist sandy loam soils in sheltered aspects, and on gentle slopes below cliff-lines near creeks in low open woodland (OEH, 2019p). Records occur in nine sites in the Hornsby-Gordon area (DEWHA, 2008b; Hogbin, Peakall et al., 2000). The species has been removed as a candidate species in Wilton because: • Associated PCTs do not occur within urban capable land	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• Nominated areas occur outside species' known geographic extent			
Heleioporus australiacus	Giant Burrowing Frog	✓	✓	X	✓	Yes	*Heleioporus australiacus* is a large frog found in south-eastern NSW and Victoria. In NSW. It appears to be largely confined to the sandstone geology of the Sydney Basin and extending as far south as Ulladulla (DPIE, 2019b). Habitat comprises heath, woodland and open dry sclerophyll forest on a variety of soil types except clay soils. Breeding habitat comprises soaks or pools within first or second order streams. The species has been added as a candidate species in GPEC as it has the potential to occur within urban capable land in the Penrith Lakes area. Targeted habitat assessments were undertaken for this species, the species was not recorded however suitable habitat was found to occur.	No	No	N/A
Hibbertia fumana		✓	✓	✓	✓	Yes	*Hibbertia fumana* is a shrub found only in the Sydney basin (OEH, 2020b). Habitat comprises intergrade sand-clay soils primarily in areas with a scribbly gum-dominated overstorey which may also have some ironbarks. The species is only known from the Moorebank and Bankstown areas. The species is recently described and if present, could have been recorded under a different name in previous studies.	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Within urban capable lands, habitat may occur in the Kemps Creek area. The species was retained as a candidate species in WSA and GPEC because suitable habitat may occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.			
Hibbertia puberula		✓	✓	✓	✓	Yes	*Hibbertia puberula* is a shrub found from Wollemi National Park south to Morton National Park and the south coast near Nowra. Habitat comprises sandy soil often associated with sandstone, or on clay within dry sclerophyll woodland communities (OEH, 2019q). One of the recently (2012) described subspecies also favours upland swamps. Within urban capable lands, habitat may occur in the Kemps Creek and Glenfield areas and the margins of Wilton. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.	Yes	No	N/A
Hibbertia sp. Bankstown		X	R	R	R	No	*Hibbertia* sp. *Bankstown* is a shrub known to occur in only one population at Bankstown Airport in Sydney.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Habitat comprises tertiary alluvial soil along Airport Creek within an area likely to have comprised Cooks River/Castlereagh Ironbark Forest. The species does not occur in areas where fill has been deposited (OEH, 2019r). The species is not known to occur in the Plan Area (although it occurs in the Cumberland subregion). Surveys for *H. fumana* and *H. puberula* have not identified this species within urban capable lands. The species has been removed as a candidate species in GMAC, WSA and GPEC because species' microhabitats are considered absent from urban capable lands. Potential habitat within the nominated areas is only likely to occur outside urban capable lands. Species is also known to be highly restricted in distribution to a single known population.			
Hibbertia spanantha	Julian's Hibbertia	R	R	X	R	No	*Hibbertia spanantha* is a shrub restricted to the Turramurra - Beecroft - Macquarie Park region. Habitat comprises forest with canopy species including *Eucalyptus pilularis, E. resinifera, Corymbia gummifera,* and *Angophora costata* (OEH, 2019s). The species is known from three populations (in three proximate Sydney suburbs within the Lane Cove River catchment (DoE, 2016a; Toelken & Robinson, 2015)).	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							The species was removed as a candidate species in Wilton, GMAC, and GPEC as urban capable lands occur outside the geographic extent of the species.			
Hibbertia superans		R	R	X	R	No	*Hibbertia superans* is a shrub in the north-west Sydney region between Baulkham Hills and Wisemans Ferry and near Blaxland in the lower Blue Mountains. It is also known from a disjunct occurrence near Mt Boss (inland from Kempsey). Habitat comprises dry sclerophyll forest on sandstone ridgetops (Royal Botanic Gardens & Domain Trust, 2019). All records of the species are to the north and east of the Plan Area. The species was removed as a candidate species in Wilton, GMAC, and GPEC as urban capable lands occur outside the geographic extent of the species.	No	No	N/A
*Hieraaetus morphnoides**	Little Eagle	✓	✓	✓	✓	Yes	*Hieraaetus morphnoides* is a bird found throughout the Australian mainland except the most densely forested parts of the Dividing Range escarpment. Habitat comprises open eucalypt forest, woodland or open woodland (OEH, 2019w). The species requires tall trees within a remnant patch in which to build a large stick nest. Stick nests have been recorded during surveys undertaken for this project. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands.	No	Yes	GPEC, GMAC, WSA

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							An expert report has been prepared to confirm whether suitable habitat exists for this species within Wilton and GMAC. Targeted surveys for breeding habitat were undertaken within the nominated areas, however no potential habitat was recorded.			
*Hoplocephalus bungaroides**	Broad-headed Snake	R	R	X	X	No	*Hoplocephalus bungaroides* is largely confined to sandstones, including the Hawkesbury, Narrabeen, and Shoalhaven groups, in an area within approximately 250 km of Sydney. Habitat comprises rock crevices and sandstone rock areas on exposed cliff edges. The species moves from sandstone rocks to shelters in crevices or hollows in large trees within 500m of escarpments in summer (OEH, 2019g). There is a single record from Appin in the Plan Area (1970), and a few other records in other parts of the Cumberland subregion. The records are poorly geolocated. The species was removed as a candidate species in Wilton and GMAC because species breeding habitat constraints (as listed in TBDC) do not occur within urban capable lands.	No	No	N/A
Lasiopetalum joyceae		R	X	X	X	No	*Lasiopetalum joyceae* is a shrub with a restricted range. It is found on lateritic to shaley ridgetops on the Hornsby Plateau south of the Hawkesbury River. Habitat comprises heath areas on sandstone (OEH, 2019u). It is	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							known from 34 sites between Berrilee and Duffys Forest (NSW Scientific Committee, 1999c). The species was removed as a candidate species in Wilton because: • Associated PCTs do not occur within urban capable land • Nominated areas occur outside species' known geographic extent			
*Lathamus discolor**	Swift parrot*	R	R	R	✓	Yes	*Lathamus discolor* is a small bird that breeds in Tasmania during the summer and migrates north to mainland Australia for the winter (TSSC, 2016). The species was removed as a candidate species in Wilton, GMAC and WSA, but maintained as a candidate in GPEC, based on the presence/absence of Mapped Important Areas for the species in urban capable lands.	No	Yes	Wilton
Leucopogon exolasius		R	X	R	R	No	*Leucopogon exolasius* is a shrub restricted to the Woronora and Grose Rivers and Stokes Creek, Royal National Park. Habitat comprises sandy alluvium and rocky sandstone hillsides near creeks, on low nutrient soils (Royal Botanic Gardens & Domain Trust, 2019).The descriptive text for many of the records within the Cumberland subregion suggest the records are inaccurately geolocated and unlikely to occur	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							within the subregion (apart from the few records near Jordan Pass, south of Appin). Potential habitat for the species within the nominated areas is likely to occur only in areas outside urban capable lands. The species was removed as a candidate species in Wilton, WSA and GPEC because associated PCTs do not occur in urban capable land.			
Leucopogon fletcheri subsp. *fletcheri*		R	R	X	R	No	*Leucopogon fletcheri* subsp. *fletcheri* is a shrub endemic to north-western Sydney and is found between St Albans in the north and Annangrove in the south (OEH, 2017g). Habitat comprises dry eucalypt woodland or shrubland on clayey lateritic soils, generally on flat to gently sloping terrain along ridges and spurs (OEH, 2017g). There are four records from the area east and north-east from Kentlyn in the sandstone ridge terrain and the species is found elsewhere in similar terrain. Despite the potential to occur in Wilton and southern part of GMAC, the habitat has been well surveyed previously and no additional records were located. The species was removed as a candidate species in Wilton, GMAC and GPEC because: • Species' microhabitats considered absent from urban capable lands	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• The species has only ever been recorded in the far northern portion of the Cumberland IBRA subregion, and records occur as historic and highly inaccurate records (based on BioNet as-held data export)			
Limicola falcinellus	Broad-billed Sandpiper	X	X	R	X	No	*Limicola falcinellus* is a small migratory bird that breeds in northern Siberia and overwinters in Australia (OEH, 2019f). The species does not breed in Australia and there is no breeding habitat or important habitat within the Plan Area. Foraging habitat significant to the species primarily comprises coastal wetlands and mudflats. The species was removed as a candidate species in WSA as important mapped areas do not occur within the nominated areas.	No	No	N/A
*Limosa limosa**	Black-tailed Godwit*	X	X	R	X	No	*Limosa limosa* is a migratory wading bird that breeds in Mongolia and eastern Siberia and spends the southern summer in Australia. In NSW, it has been recorded at Kooragang Island. The species does not breed in Australia and there is no breeding habitat within the Plan Area. Non-breeding habitat is predominantly coastal areas including sheltered bays, estuaries, and lagoons. It can also be found further inland on mudflats and around muddy lakes and swamps (OEH, 2019e). There are 10 records in the Cumberland subregion	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							mostly from between 1980 and 1992. Sighting locations include lagoons in the northern parts of the Plan Area (e.g. Bakers Lagoon) outside urban capable lands. The species was removed as a candidate species in WSA as important mapped areas do not occur within the nominated areas.			
Litoria aurea	Green and Golden Bell Frog	✓	✓	✓	✓	Yes	*Litoria aurea* is a large frog formerly distributed from the NSW north coast near Brunswick Heads, southwards along the NSW coast to Victoria (OEH, 2019o). Habitat comprises marshes, dams and stream-sides, particularly those containing bulrushes (*Typha* spp.) or spikerushes (*Eleocharis* spp.). Primary habitat includes waterbodies that are unshaded, free of predatory fish, and have a grassy area nearby. Records of the species within the nominated areas are scattered and generally old or poorly geolocated. Two recent records (2013, 2015) in the Blair Athol area near Campbelltown suggest that the species can persist in heavily impacted environments. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Targeted habitat assessments have not been undertaken for this species.			
*Lophoictinia isura**	Square-tailed kite	✓	✓	✓	✓	Yes	*Lophoictinia isura* is a medium-sized bird found in coastal and subcoastal areas from south-western to northern Australia, Queensland, NSW and Victoria. It is known to occur in the Cumberland subregion. Habitat comprises dry woodlands and open forests, in particular timbered watercourses (OEH, 2017j). Stick nests that may be associated with this species have been recorded during field surveys for this project The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within Wilton and GMAC. Targeted surveys for breeding habitat were undertaken within the nominated areas and potential habitat was recorded.	Yes	Yes	GMAC, GPEC
Marsdenia viridiflora subsp. *viridiflora - endangered population*		X	✓	✓	✓	Yes	*Marsdenia viridiflora* subsp. *viridiflora* is a climbing plant. The distribution of the population within the relevant local government areas described in the final determination is not clearly defined. Habitat comprises vine thickets and open shale woodland (OEH, 2019x). Recent records occur in Narellan, Mt Annan Botanic	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Gardens, and the Western Sydney Airport. Recent survey in the Menangle area did not record the species. The species may occur in the Gilead area of GMAC. Habitat for the species will be modelled to determine impacts. The species was retained as a candidate species in all GMAC, WSA and GPEC because suitable habitat has the potential to occur in urban capable lands.			
Maundia triglochinoides		X	X	✓	✓	Yes	*Maundia triglochinoides* is a water plant restricted to coastal NSW and extending into southern Queensland. Habitat comprises swamps, lagoons, dams, channels, creeks or shallow freshwater 30 to 60 cm deep on heavy clay with low nutrients (OEH, 2019z).There is a single record in the Cumberland subregion that is highly questionable as it occurs in very weedy habitat. Other records in the Sydney area are from coastal sites and wetlands that occur outside urban capable lands. Detailed habitat assessments have been undertaken. The species was retained as a candidate species in WSA and GPEC due to the presence of high Strahler order streams (e.g. Wianamatta (South Creek)) in suitable PCTs.	No	No	N/A
Melaleuca deanei	Deane's Paperbark	✓	✓	X	R	Yes	*Melaleuca deanei* is a shrub found in two distinct areas – in the north (Ku-ring-gai/Berowra area) and south (Holsworthy/Wedderburn area) of Sydney. There are	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							also more isolated occurrences in the Blue Mountains, Nowra and Central Coast areas" (NSW Scientific Committee, 1999d). Habitat mostly comprises ridgetop woodland, with about 5 per cent of sites located in heath on sandstone (OEH, 2019k). The species was retained as a candidate species in Wilton and GMAC because suitable habitat has the potential to occur in urban capable lands. The species was removed in GPEC as the expert report concluded species unlikely to be present in GPEC nominated area. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.			
Meridolum corneovirens	Cumberland Plain Land Snail	✓	✓	✓	✓	Yes	*Meridolum corneovirens* is a snail that is found on the Cumberland Plain from Richmond and Windsor south to Picton, and from Liverpool west to the Hawkesbury and Nepean Rivers. Habitat comprises the litter of bark, leaves and logs, or shelters in loose soil around grass clumps within Cumberland Plain Woodland and Shale Gravel Transition Forest, Castlereagh Swamp Woodlands and the margins of River-flat Eucalypt Forest (OEH, 2019j). The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands.	Yes	Yes	GPEC, GMAC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record

							An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.			
Micromyrtus minutiflora		X	X	✓	✓	Yes	*Micromyrtus minutiflora* is a shrub restricted to the area between Richmond and Penrith. Habitat comprises Castlereagh Scribbly Gum Woodland, Ironbark Forest, Shale/Gravel Transition Forest and open forest on tertiary alluvium and consolidated river sediments (OEH, 2019aa). Records to the south-east of Wilton and Appin are likely to be misidentifications of the very similar species *M. blakelyi* and *M. ciliata.* The species was retained as a candidate species in WSA and GPEC because suitable habitat has the potential to occur in urban capable lands.	Yes	No	N/A
*Miniopterus australis**	Little Bent-wing Bat	R	R	R	R	No	*Miniopterus australis* is a micro-bat found along the east coast and ranges of Australia from Cape York in Queensland to Wollongong in NSW. Habitat comprises moist eucalypt forest, rainforest, vine thicket, wet and dry sclerophyll forest, Melaleuca swamps, dense coastal forests, and Banksia scrub. Roosting habitat includes caves, tunnels, tree hollows, abandoned mines, stormwater drains, culverts, bridges and buildings (OEH, 2019v). Breeding habitat occurs within steep and rocky areas.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							The species was removed as a candidate species in all nominated areas species' breeding microhabitats considered absent from urban capable lands. Potential breeding habitat within the nominated areas occurs only outside urban capable lands.			
*Miniopterus orianae oceanensis**	Large Bent-winged Bat	R	R	R	R	No	*Miniopterus orianae oceanensis* is a micro-bat found along the east and north-west coasts of Australia. Roosting habitat comprises caves, but also derelict mines, storm-water tunnels, buildings and other man-made structures (OEH, 2019m). Potential breeding habitat for the species (caves) within the nominated areas is likely to only occur outside urban capable lands. There are no records of any significant human-made breeding habitat within urban capable lands. The species was removed as a candidate species in all nominated areas as species' breeding microhabitats considered absent from urban capable lands.	No	No	N/A
Myotis macropus	Southern Myotis	✓	✓	✓	✓	Yes	*Myotis Macropus* is a micro-bat in the coastal band from the north-west of Australia, across the top-end and south to western Victoria. Habitat comprises caves, mine shafts, hollow-bearing trees, storm water channels, buildings, under bridges and in dense foliage (OEH, 2019ah). Records occur throughout the	Yes	Yes	GMAC, WSA

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Cumberland subregion. There have been 72 sightings of the species in the subregion since 2012. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands.			
*Ninox connivens**	Barking owl	✓	✓	R	✓	Yes	*Ninox connivens* is a medium-sized owl that occurs in a wide but sparse distribution in NSW. Core populations exist on the western slopes and plains and in some northeast coastal and escarpment forests (OEH, 2019c). Habitat comprises woodland and open forest, including fragmented remnants and partly cleared farmland. Breeding habitat comprises hollows of large eucalypts or paperbarks, usually near watercourses or wetlands (NSW NPWS, 2003b). The species was retained as a candidate species in Wilton, GMAC and GPEC because suitable habitat has the potential to occur in urban capable lands. The species was removed in WSA because • Species' breeding microhabitats considered substantially degraded within the WSA nominated area • Species has never been recorded in the WSA nominated area (based on BioNet as-held data export)	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Habitat assessment surveys have been undertaken across the Growth Ares for this species. Potential breeding habitat was found to be present.			
*Ninox strenua**	Powerful owl	✓	✓	✓	✓	Yes	*Ninox strenua* is a large owl that is occurs in eastern and south-eastern Australia, from Mackay down to Victoria. Habitat comprises a range of vegetation types, including woodland, open sclerophyll forest, tall wet open forest, and rainforest. While this species typically requires large tracts of intact woodland, it is also known to occur in fragmented landscapes. The species nests in large tree hollows (OEH, 2017h). The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. Habitat assessment surveys have been undertaken across the nominated areas for this species. Potential breeding habitat was found to be present.	Yes	Yes	GMAC
*Pandion cristatus**	Eastern Osprey	X	R	R	R	No	*Pandion cristatus* is a bird of prey that is found around the Australian coastline, except for Victoria and Tasmania, especially on rocky shorelines, islands and reefs. The species is uncommon to rare or absent from closely settled parts of south-eastern Australia. Habitat comprises coastal areas, particularly large coastal river mouths, lakes and lagoons (DPIE, 2020a). The species	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							nests in tall trees in coastal woodland to forest habitat (NSW Scientific Committee, 2009a). The breeding population of this species in NSW spans from the Queensland border to Ulladulla in south-eastern NSW. Vagrants have been recorded as far south as Victoria (NSW Scientific Committee, 2009a). There are four records in the Cumberland subregion. Three occur in Milperra in 2014 (two have the same coordinates), while the last record is from North Ryde. The species was removed as a candidate species in GMAC, WSA and GPEC because of breeding microhabitats are considered absent from urban capable lands.			
Persicaria elatior	Tall Knotweed	X	✓	✓	✓	Yes	*Persicaria elatior* is an herb found in south-eastern and northern NSW and Queensland. It is known from the Cumberland subregion. Habitat comprises damp places, particularly beside streams and lakes. The species is occasionally found in swamp forest or associated with disturbance (OEH, 2020d). There are a few records within and nearby the Plan Area. The 1949 record from 'Picton Lakes' refers to Thirlmere Lakes (at that time being called Picton Lakes), and more recent (2010) records occur there. There is an unverified record from 2018. The species has been retained as a candidate in GMAC, WSA and GPEC because it may be subject to prescribed	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							impacts (hydrology) and the transport corridors may have a direct impact on the species in WSA and GPEC. Targeted surveys have not been undertaken for this species within urban capable lands. However, habitat assessments have been completed.			
Persoonia bargoensis	Bargo Geebung	✓	✓	R	R	Yes	*Persoonia bargoensis* is a shrub that is restricted to a small area south-west of Sydney bounded by Picton, Douglas Park, Yanderra, and Cataract River. Habitat comprises woodland or dry sclerophyll forest on sandstone and shale soils. The species can be found adjacent to disturbed areas such as roadsides (OEH, 2019b). Many of the records in Wilton and GMAC have very low reliability and are not recent records. The species was retained as a candidate species in Wilton and GMAC because records occur within urban capable lands and suitable habitat has the potential to occur. The species was removed in WSA and GPEC because the two nominated areas occur outside the species' known geographic extent.	Yes	No	N/A
Persoonia glaucescens	Mittagong Geebung	R	X	X	X	No	*Persoonia glaucescens* is a shrub that is found in the Southern Highlands area, roughly between Picton and Berrima (OEH, 2002). Recent surveys have indicted this distribution has contracted (OEH, 2019ab). Habitat includes woodland to dry sclerophyll forest, mostly on	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							ridge tops, plateaux, and upper slopes (OEH, 2019ab). Records occur to the south of the Plan Area, with the northernmost records at Tahmoor. Surveys have been undertaken for this species within urban capable lands. The species was not recorded during surveys. The species was removed as a candidate species in Wilton because: • Associated PCTs do not occur within urban capable land • Nominated areas occur outside species' known geographic extent			
Persoonia hirsuta	Hairy Geebung	R	R	R	R	No	*Persoonia hirsuta* is a shrub that has a scattered distribution around Sydney, and is found in the area bounded by Bargo to the south, Singleton to the north and the Blue Mountains to the west (OEH, 2017f). Habitat comprises sandstone and sandstone-derived soils in dry sclerophyll open forest, woodland, and heath (OEH, 2017f). There are no records of the species within the Plan Area. The sole record within the Plan Area is a specimen that is misplaced and should correctly be located in 'Long Point, Macquarie Fields', approx. 3 km south-east of the mapped location. The species was removed as a candidate species in all nominated areas because:	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							• Species' microhabitats considered absent from urban capable lands • Nominated areas occur outside species' known geographic extent			
Persoonia mollis subsp. *maxima*	Soft Geebung	R	X	X	X	No	*Persoonia mollis* subsp. *maxima* is a tall shrub with a restricted distribution and is known from the Hornsby Heights - Mt Colah area north of Sydney (OEH, 2019ae). Habitat comprises sheltered, deep Hawkesbury sandstone gullies and upper steep hillsides (OEH, 2019ae). These habitats often support relatively moist, tall forest vegetation communities, often with warm temperate rainforest influences (OEH, 2019ae). There 11 records within the Cumberland subregion. All records occur outside the nominated areas. The most recent record is 2005. The species was removed as a candidate species in Wilton because: • Associated PCTs do not occur within urban capable land • Nominated areas occur outside species' known geographic extent	No	No	N/A
Persoonia nutans	Nodding Geebung	R	R	✓	✓	Yes	*Persoonia nutans* is a shrub that is found on the Cumberland Plain, between Richmond in the north and Macquarie Fields in the south. Core distribution occurs in Penrith, and to a lesser extent the Hawkesbury area.	Yes	Yes	GPEC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Northern populations are found on aeolian and alluvial sediments, while southern populations occur on alluvial sediments and shale/sandstone transition zones. Habitat comprises a range of sclerophyll forest and woodland vegetation communities (OEH, 2019ac). Records in the northern end of GMAC are poorly geolocated. More accurate records occur in the Simmos Beach and Moorebank area The species was retained as a candidate species in WSA and GPEC because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands. The species was removed as a candidate species in Wilton and GMAC because the expert report confirmed a lack of suitable habitat within urban capable lands.			
Petaurus norfolcensis	Squirrel Glider	✓	✓	R	✓	Yes	*Petaurus norfolcensis* is a small possum that is found in eastern Australia from northern Queensland to western Victoria. Habitat comprises blackbutt-bloodwood forest with heath understorey in coastal areas, and box, box-ironbark, and river red gum woodlands further inland (OEH, 2017k). The species prefers mature or old growth woodland and requires abundant tree hollows for	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							refuge and nesting sites (OEH, 2017k). Records occur within Wilton in areas outside urban capable lands. The species was retained as a candidate species in Wilton, GMAC and GPEC because suitable habitat has the potential to occur in urban capable lands. The species was removed in WSA because: • Species' microhabitats considered substantially degraded within the WSA nominated area • Species has never been recorded in the WSA nominated area (based on BioNet as-held data export) Habitat assessment surveys have been undertaken across the nominated areas for this species. Potential habitat was found to be present.			
*Phascolarctos cinereus**	Koala	✓	✓	R	R	Yes	*Phascolarctos cinereus* is an arboreal marsupial that has a fragmented distribution throughout eastern Australia. In NSW, it mainly occurs on the central and north coasts with some populations in the west of the Great Dividing Range. Habitat comprises eucalypt woodlands and forests. Koalas feed on over 70 species of Eucalyptus and over 30 non-Eucalyptus species (OEH, 2018a). There are a significant number of recent Koala records present within and adjacent to Wilton and GMAC. Breeding habitat occurs through the eastern portion of GMAC and around Wilton (DPIE,	Yes	Yes	GMAC, Wilton

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							2019a). Records further indicate the presence of Koalas within the Blue Mountains, particularly in the district of Kurrajong, with very few records occurring east of these areas within the urban matrix. The TBDC says the following in relation to important habitat for Koalas: "'Important' habitat (however this is not a mapped important habitat area) is defined by the density of Koalas and quality of habitat determined by on-site survey - contact OEH for more information". Important habitat for the species was identified in GMAC and Wilton and is represented by the mapping of primary, second, and tertiary corridors. See Section 11.5.4 in Chapter 11 for a description of the mapping methods for Koala and the The species was retained as a candidate species in Wilton and GMAC because of the high density of records and the presence of important habitat. The species was removed in WSA and GPEC because of limited records and a lack of important habitat within these nominated areas. See Section A.2 below this table for a detailed discussion about the justification for excluding koalas from WSA and GPEC.			
Pilularia novae-hollandiae	Austral Pillwort	X	R	R	R	No	*Pilularia novae-hollandiae* is a semi-aquatic fern that has a scattered distribution in NSW. Habitat comprises shallow swamps and waterways, often amongst grasses	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							and sedges. The species is probably ephemeral, growing in moist soils following rain events, and is often recorded in drying mud (OEH, 2018b). Despite the high occurrence and coverage of botanical surveys across the Cumberland subregion the species has not been recorded since a single record from 1966 in Doonside. It is expected that more recent records would exist if the species natural range included the Cumberland subregion. Potential habitat for the species (high order Strahler streams) within the nominated areas is likely to only occur in areas outside urban capable lands, with all mapped creek lines above Strahler order one, being excluded from the footprint. The species has been removed as a candidate in all nominated areas because: • Species' microhabitats considered absent from urban capable lands • Species considered extinct within the geographic extent of the nominated areas			
Pimelea curviflora var. *curviflora*		R	R	R	✓	Yes	*Pimelea curviflora* var. *curviflora* is a shrub found in the coastal area of Sydney and the Illawarra regions (OEH, 2019af).The species is known from approximately 20 locations in the Baulkham Hills, Blacktown, Hornsby, Parramatta and Warringah Local Government Areas	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							(NSW NPWS, 1999) and the Shellharbour area. The species was formerly recorded around the Parramatta River and Port Jackson areas. Habitat comprises shale, sandstone, and lateritic soils, on ridgetops and upper slopes in woodlands (OEH, 2019af). Records (dated 2000) occur in only two locations in the vicinity of the nominated areas. Despite extensive surveys at Bingara Gorge in suitable habitat, the species was not recorded, suggesting that the two records in the vicinity of the nominated areas may be misapplications for *P. curviflora* var. *sericea* which is recorded in that area. The species was retained as a candidate species in GPEC because records or suitable habitat potentially occur in the vicinity of urban capable lands. The species was removed in Wilton, GMAC and WSA because the nominated areas occur outside species' known geographic extent.			
Pimelea spicata	Spiked Rice-flower	✓	✓	✓	✓	Yes	*Pimelea spicata* is a shrub that occurs in two disjunct areas; the Cumberland Plain (Marayong and Prospect Reservoir south to Narellan and Douglas Park) and the Illawarra (Lansdowne to Shellharbour to northern Kiama) (OEH, 2019ai). Habitat comprises Grey Box communities (particularly Cumberland Plain Woodland variants and Moist Shale Woodland) and in areas of ironbark on well-structured clay soils (OEH, 2019ai). Nearest records to the nominated areas are	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							around Douglas Park. It is likely that the species no longer occurs in the parts of the nominated areas due to a history of intensive grazing and other land uses. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands. While the species was not recorded during surveys for this project, suitable habitat was recorded.			
Pomaderris brunnea	Brown Pomaderris	✓	✓	R	R	Yes	*Pomaderris brunnea* is a shrub that is found in restricted areas near the Colo, Nepean, and Hawkesbury rivers in NSW, in addition to areas near Bargo and Camden. It is also known near Walcha in the New England Tablelands, and from Gippsland in Victoria. Habitat comprises moist woodland or forest on clay and alluvial soils of flood plains and creek lines (OEH, 2019h). Records occur in several areas within the GMAC, particularly to the south of Menangle Creek in the Gilead area and on Beulah Biobank site. One of the records adjacent to Wilton appears to be poorly geolocated. The species was retained as a candidate species in Wilton and GMAC because records or suitable habitat	Yes	Yes	GMAC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							occurs in the vicinity of urban capable lands. The species was removed in WSA and GPEC because: • The nominated areas occur outside species' known geographic extent • Of a lack of records and suitable clay and alluvial soils within urban capable lands			
Pomaderris prunifolia - endangered population		R	X	R	R	No	*Pomaderris prunifolia* is a shrub that occurs uncommonly on the tablelands and slopes of NSW. A population of the species within the Parramatta, Auburn, Strathfield, and Bankstown Local Government Areas is listed as endangered. The population is known from only three sites – at Rydalmere on a road reserve, within Rookwood Cemetery and at The Crest of Bankstown (OEH, 2019ad). The species was removed as a candidate species in Wilton, WSA and GPEC because the extent of the population does not occur within urban capable lands.	No	Yes	GMAC
Pommerhelix duralensis	Dural Land Snail	R	R	R	R	No	*Pommerhelix duralensis* is a medium sized snail endemic to NSW where it occurs on the northwest fringes of the Cumberland subregion. Habitat comprises shale-sandstone transitional landscapes. Most of the records for the species occur around the towns of Wisemans Ferry, Maraylya, Glenorie, and Dural (DoE, 2015a). The species occurs primarily northwards from Lake Parramatta through Dural and Kentlyn towards the	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							Hawkesbury River. Records from west and south of the GPEC are likely errors (S. Clark pers. comm.) or relate to different taxa (C. Allen pers. comm.). The species was removed as a candidate species in all nominated areas as urban capable lands are outside the geographic extent of the species.			
Pseudophryne australis	Red-crowned Toadlet	✓	✓	X	✓	Yes	*Pseudophryne australis* is small frog that occurs in the Sydney Basin. Habitat comprises periodically wet drainage lines in open forests on Hawkesbury and Narrabeen Sandstones (OEH, 2019ag). There are a number of records of the species within the vicinity of three of the nominated areas. The species was retained as a candidate species in Wilton, GMAC and GPEC because suitable habitat has the potential to occur in urban capable lands. Targeted habitat assessments were undertaken for this species, the species was not recorded however suitable habitat was found to occur.	No	No	N/A
*Pteropus poliocephalus**	Grey-headed flying fox	R	R	R	R	No	*Pteropus poliocephalus* is a large bat that is found along the eastern coast of Australia. Habitat comprises a range of forests, woodlands, heaths, and swamps as well as urban gardens and fruit crops (OEH, 2018f). The location of breeding and roosting sites within the Cumberland subregion has been monitored since 2012 as part of a national program (DAWE, 2021).	Yes	Yes	GMAC, GPEC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							The species was removed as a candidate species in in all nominated areas because there are no known breeding sites in urban capable lands.			
Pterostylis saxicola	Sydney Plains Greenhood	✓	✓	R	✓	Yes	*Pterostylis saxicola* is an orchid that is restricted to western Sydney between Freemans Reach in the north and Picton in the south. Habitat comprises sandstone outcrop areas in shale-sandstone transition forest, although it is occasionally found on clay-rich sites (OEH, 2018j). There are a number of records in the vicinity of the nominated areas. Some of these are thought to have low reliability in terms of their location. The species was retained as a candidate species in Wilton, GMAC and GPEC because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands. The species was removed as a candidate species in WSA because the expert report concluded the species unlikely to be present.	Yes	No	N/A
Pultenaea parviflora		X	X	✓	✓	Yes	*Pultenaea parviflora* is a small shrub that is endemic to the Cumberland Subregion. The species primarily occurs in areas of Shale Gravel Transition Forest and Cooks River/ Castlereagh Ironbark Forest, with some	Yes	Yes	WSA, GPEC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record

							potential in Castlereagh Scribbly Gum Woodland and Castlereagh Swamp Forest (OEH, 2017i). The species was retained as a candidate species in WSA and GPEC because records occur in the vicinity of the nominated areas and suitable habitat has the potential to occur in urban capable lands.			
Pultenaea pedunculata	Matted Bush-pea	✓	✓	✓	✓	Yes	*Pultenaea pedunculata* is a shrub that occurs in NSW, Victoria, and Tasmania. In NSW it occurs in three locations including the Cumberland Subregion. The species occurs in a range of habitats and in the Cumberland Subregion it favours clay or sandy-clay soils that have a lateritic influence with ironstone gravel (nodules) present (OEH, 2018h). The species has been recorded in several places in the vicinity of the nominated areas. The species was retained as a candidate species in all nominated areas because records occur in the vicinity of the nominated areas and suitable habitat has the potential to occur in urban capable lands.	Yes	No	N/A
Tetratheca glandulosa		R	R	X	R	No	*Tetratheca glandulosa* is a small shrub that is restricted to the following Local Government Areas (LGAs): Baulkham Hills, Gosford, Hawkesbury, Hornsby, Ku-ring-gai, Pittwater, Ryde, Warringah, and Wyong (the nominated areas do not occur in these LGAs). The	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
							species has a strong association with shale-sandstone soils (OEH, 2017l). The nearest substantiated records to the nominated areas are to the west of Thirlmere lakes where they occur on sandstone communities outside urban capable lands. The species was removed as a candidate species in Wilton, GMAC and GPEC because urban capable lands are outside the geographic range of the species and no records of the species occur within the vicinity.			
Thesium australe	Austral Toadflax	R	R	R	R	No	*Thesium australe* is a small herb that is found in small populations along the coast of NSW. The species occurs in grasslands on the coast, and grassland or grassy woodland further inland (OEH, 2018c). The species is distinctive in survey (sprawling yellow-grey-green herb) and has only a single old record (1803) from the Cumberland subregion (which is also the type collection). It is currently considered to be extinct in the subregion (OEH, 2018c). The species was removed as a candidate species in all nominated areas because urban capable lands are outside the geographic range of the species and no reliable records of the species occur within the vicinity.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Tyto novaehollandiae (breeding)	Masked Owl	✓	✓	R	✓	Yes	*Tyto novaehollandiae* is a medium-sized owl which occurs over 90 per cent of NSW and is most abundant on the coast. Roosting and breeding habitat for the species comprises moist eucalypt forested gullies, and it uses large tree hollows or caves for nesting (OEH, 2019y). The large-scale breeding habitat and the fairly specific requirements of large, hollowed trees (and especially hollowed stag trees) are scarce on the Cumberland subregion. The species was removed as a candidate species in WSA because: • Species' breeding microhabitats considered substantially degraded within the WSA nominated area • Species has never been recorded in the WSA nominated area (based on BioNet as-held data export) The species was retained as a candidate species in Wilton, GMAC and GPEC because known sites occur within the vicinity of the nominated areas. Habitat assessment surveys have been undertaken across the Growth Ares for this species. Potential breeding habitat was found to be present.	Yes	No	N/A

endangered population							Sydney (Rookwood, Chullora, Bass Hill, Bankstown, Georges Hall, Campsie, South Granville and Greenacre) (OEH, 2019aj). In Western Sydney, habitat is associated with the Villawood Soil Series, which is a poorly drained, yellow podsolic extensively permeated with fine, concretionary ironstone (laterite). The species was removed as a candidate species in all nominated areas because the population does not occur within urban capable lands.			
Zannichellia palustris	Horned Pondweed	X	X	R	X	No	*Zannichellia palustris* is a submerged aquatic plant. In NSW it is only known from the lower Hunter region and Sydney Olympic Park. It occurs in fresh or slightly saline stationary or slowly flowing water (OEH, 2017m). The species was removed as a candidate species in WSA because urban capable land is outside the geographic extent of the species.	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC					
Zieria involucrata		R	X	X	X	No	*Zieria involucrata* is a small shrub that occurs to the north and west of Sydney in the Baulkham Hills, Hawkesbury, Hornsby, and Blue Mountains Local Government Areas. The species is associated with Hawkesbury sandstone, as well as Narrabeen Group sandstone and Quaternary alluvium (OEH, 2017n). The Cumberland subregion occurs within the predicted distribution of the species (OEH, 2017n), and there is one old record from Kurrajong in 1959. The species was removed as a candidate species in Wilton because urban capable land is outside the geographic extent of the species.	No	No	N/A

* These species are SCS in relation to breeding habitat or mapped "important habitat" only

A.2 JUSTIFICATION FOR EXCLUDING KOALA IN GPEC AND WSA

As identified in Table A-1 above, Koala was excluded as a candidate SCS in Greater Penrith to Eastern Creek Investigation Area (GPEC) and Western Sydney Aerotropolis (WSA). This was determined based on consideration of best available ecological data as provided by Section 6.1.1.2 of the BAM, and:

- The context for assessing Koalas under the BAM
- Habitat mapping for the species
- Consideration of threatening processes
- Consideration of distribution of Koala records

A.2.1 CONTEXT FOR ASSESSING KOALAS UNDER THE BAM

The NSW Threatened Biodiversity Data Collection says the following in relation to important habitat for Koalas: "'Important' habitat (however this is not a mapped important habitat area) is defined by the density of Koalas and quality of habitat determined by on-site survey - contact OEH for more information".

A.2.2 HABITAT MAPPING WITHIN GPEC AND WSA

While Koala was excluded as a candidate species in GPEC and WSA, mapping was undertaken for the species within these nominated areas. This mapping informed the decision to exclude Koala as a candidate species from these areas.

Three methods of mapping (see Section 11.5.4) were conducted to determine the availability and importance of Koala habitat within GPEC and WSA as follows:

- The first method, known as a Species Distribution Model (SDM), did not find any areas of potential Koala habitat within either GPEC or WSA. See Supporting Document F for further information
- The second method, known as corridor mapping, was based on the same approach for mapping Koala habitat as developed and used in GMAC and Wilton. This mapping found only scattered areas of supporting Koala habitat within GPEC or WSA and did not identify any 'important habitat' (defined as primary, secondary, or tertiary corridors – see Section 11.5.4). A key driver of this result was the general lack of Koala records within and around GPEC and WSA (see Section A.2.4 below). The lack of important habitat is a key justification for excluding the species from GPEC and WSA
- The third method, known as habitat critical to the survival mapping, did not map any habitat critical in GPEC or WSA

A.2.3 CONSIDERATION OF THREATENING PROCESSES

GPEC already contains large areas of existing urban development. Urban environments pose significant threats to Koalas, through factors including high road and traffic densities, high densities of predators such as domestic dogs, landscape hazards such as swimming pools and barriers to movement such as fences. Whilst Koalas may very occasionally occur within areas of vegetation within GPEC, it is considered highly unlikely that a breeding and persisting population of Koalas would be able to permanently reside in habitat within GPEC, as it is likely that the mortality rates of Koalas due to the high threat pressures would be greater than the breeding rate.

WSA does not currently have such a high density of urban development, and therefore is less likely to have threat densities which are as significant as those in GPEC. However, the scarcity of native vegetation within the nominated area would require Koalas to cross large areas of open habitat whilst traversing between vegetation, which would increase the vulnerability of Koalas to threats such as predation by dogs.

Overall, it is considered that significant threats would be present within both GPEC and WSA.

A.2.4 CONSIDERATION OF KOALA RECORD DISTRIBUTION

The BioNet record database was examined to determine the likelihood that Koalas are present within GPEC and WSA. An area encompassing the two nominated areas and 2 km around each nominated area was investigated. It is noted that there are high human population densities in both areas, particularly within GPEC, and therefore an absence of records would be likely to accurately reflect an absence of Koalas (as opposed to an absence of surveys).

For context there are:

- 2,228 records within 2 km of Greater Macarthur GA
- 479 records within 2 km of Wilton GA

RECORDS WITHIN 2 KM OF WSA

There are no records of Koalas within 2 km of WSA. This supports the species being excluded and does not support Koalas occurring in sufficient 'density' (as referenced by the TBDC) for there to be 'important habitat' within the nominated area.

RECORDS WITHIN 2 KM OF GPEC

There are 14 records within 2 km of GPEC. These are shown in Figure A-1 and described in Table A-2. The table has the attributes from the records, with additional comments in the last column.

Of the 14 records within 2 km of GPEC, two occur within the nominated area (#s 13 and 14). Both records occur in highly developed areas of GPEC and are questionable in their relevance:

- Record 13 is 30+ years old, and is possibly a north coast record as the animal was taken to Coffs Harbour Koala Park
- Record 14 is 5 years old, has a low level of accuracy (suburb only), and may also possibly be a north coast record as Oxley Park may refer to Port Macquarie (records in western Sydney have been corrected to Port Macquarie in the past)

Four of the records occur to the north of GPEC. They are #s 9-12:

- Records 9 and 10 occur 1 week apart in 2018 and may be the same animal. Record 9 is of a Koala trapped in a yard by a domestic dog which was rescued by WIRES, and record 10 is of a Koala that was killed on Stony Creek Road
- Record 11 is from the same date as record 10 and has a low level of accuracy (suburb only). This is a wildlife rehabilitation record, indicating it is likely to be associated with an injured Koala. It may be related to records 9 and 10
- Record 12 is of a scat from 2006

Eight of the records occur to the west of GPEC. They are #s 1-8:

- Records 1 and 2 are from 2018 and occur 1.1km to the west of GPEC. They have a high level of accuracy
- Records 3, 4 & 5 are more than 20 years old. Record 3 has very poor accuracy, and record 5 occurs to the west of the Nepean
- Record 6 is 3 years old but is suburb only
- Records 7 and 8 are more than 20 years old and occur to the west of the Nepean River

In summary, based on this review of records:

- The number and quality of records does not support Koalas occurring in sufficient 'density' (as referenced by the TBDC) for there to be 'important habitat' within GPEC
- It appears highly unlikely that Koalas occur regularly (if at all) in GPEC. There are no records with a reasonable level of confidence in the nominated area, there are no records from Wianamatta Regional Park, and no records from Mulgoa Nature Reserve (just outside GPEC). These areas are near urban areas and are well traversed, so it is unlikely that there are present yet unrecorded Koalas
- There are very few records to the north, and the three records from 2018 may be the same animal. All these records indicate a Koala in distress (being attacked by a dog, a roadkill record, and a wildlife rehabilitation record). Note that this animal apparently did not survive for long in this environment
- There are only 2 records to the west of GPEC that have a reasonable level of confidence that also occur to the east of the Nepean. The Nepean is likely to represent a significant barrier to dispersal

A.2.5 CONCLUSION

The review of records and habitat, and the high level of existing threats supports the conclusion that Koalas should be excluded as candidate species credit species within both GPEC and WSA. This is consistent with the TBDC reference to important habitat relating to the density of Koalas (low to nil in both nominated areas) and quality of habitat (mapped as supporting only with high levels of threat

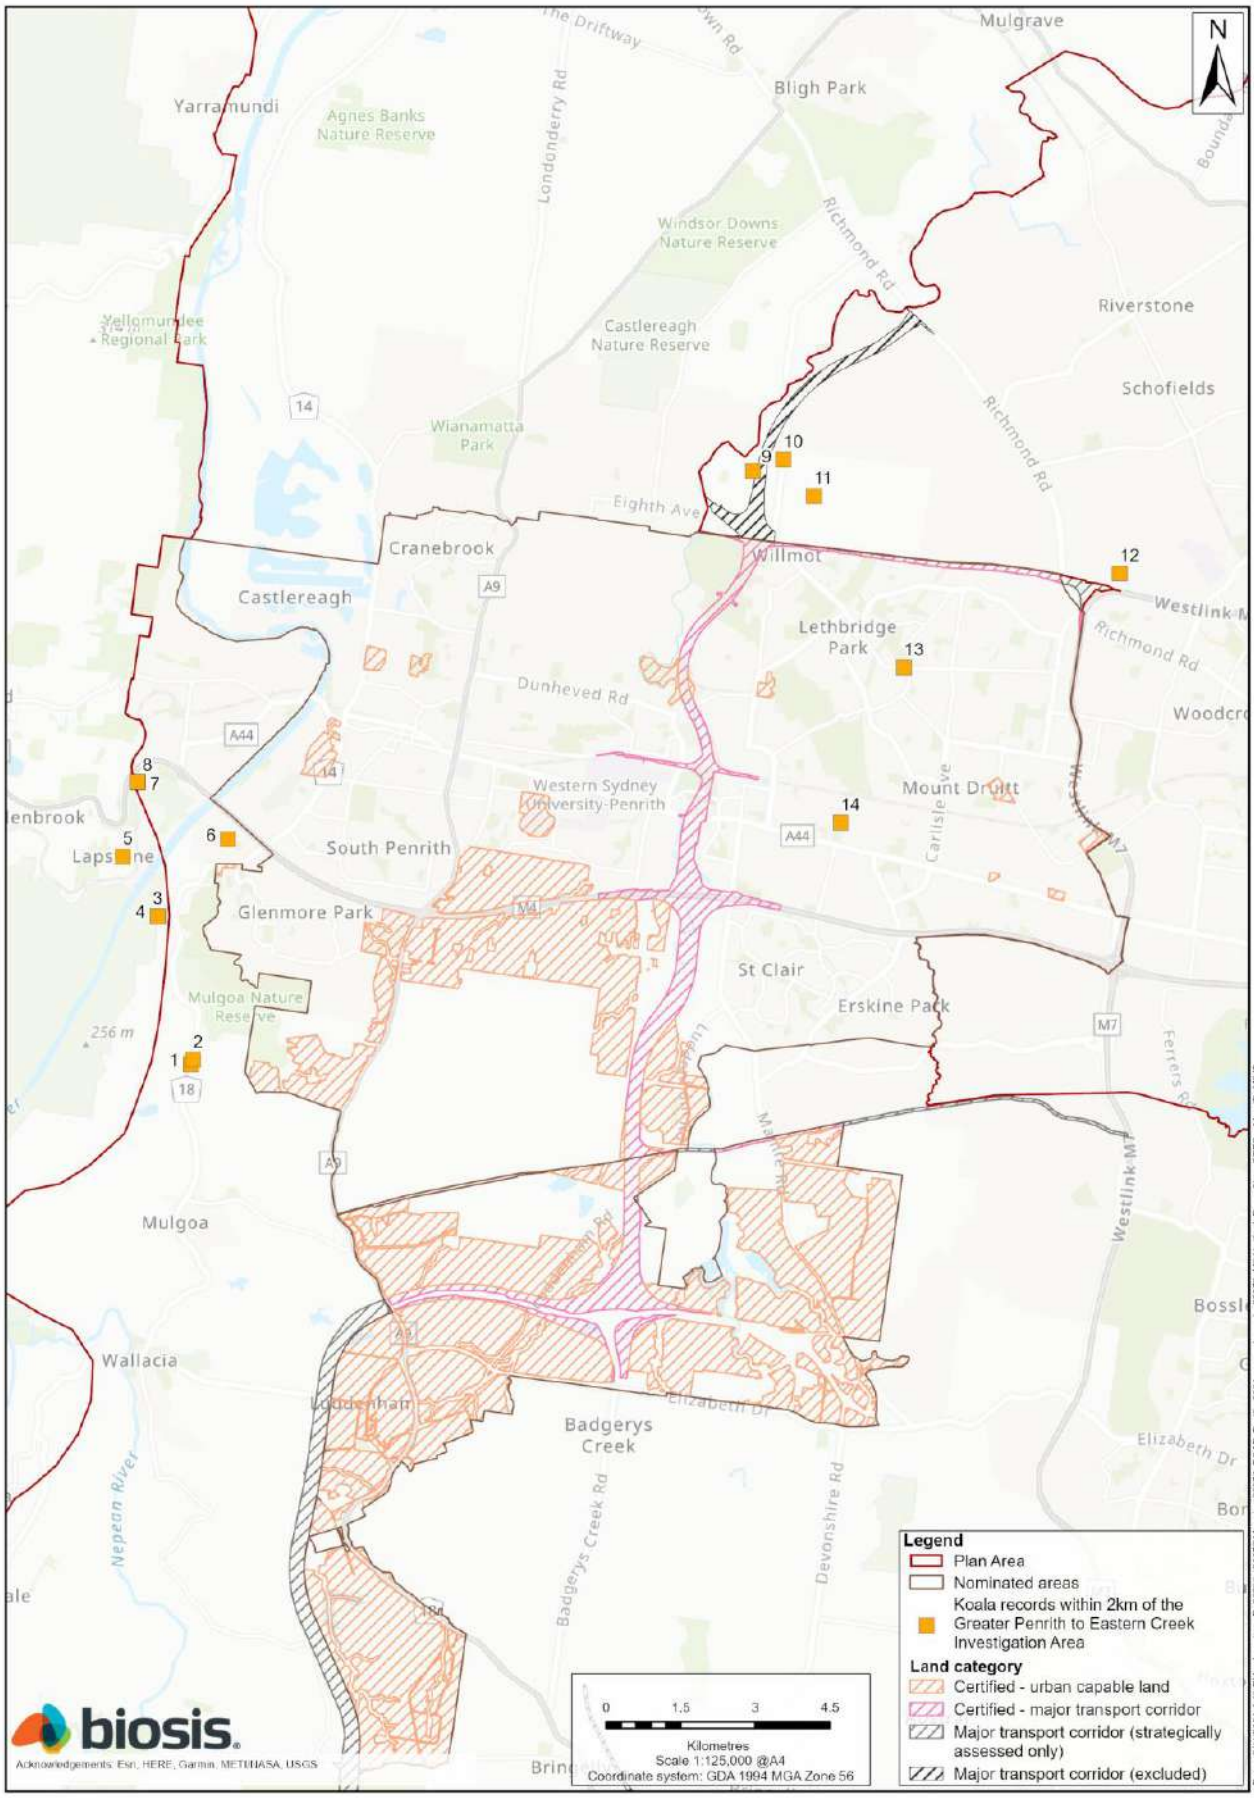

Figure A-1: Koala records within 2 km of GPEC

Table A-2: Description of BioNet Koala records within 2 km of GPEC

ID	First Date	Last Date	Number of Individuals	Observation	Description	Accuracy	Sighting Notes	Location Notes	Notes
1	22/4/18	22/4/18	0	O - Seen	Mulgoa Road, Mulgoa running beside safety barrier just south of 750 Mulgoa Road heading east; later observed again on Mulgoa Road	100			Record 3.5 years old High level of accuracy Record lies 1.1 km to the west of GPEC
2	24/6/18	24/6/18	1	O - Seen	Mulgoa road - in between Nepean Christian school and Notre Dame, on the left-hand side of the road if you are heading towards Wallacia Mulgoa	1000			Record 3 years old High level of accuracy (description provided) Record lies 1.1 km to the west of GPEC
3	1/11/99	31/12/99	0	O - Seen		10000			Record 20+ years old Very poor accuracy
4	1/12/99	1/12/99	1	O - Seen	Glenbrook Specified Map No: 9030	1000	Saw Koala in a tree. Observer a participant in the Lower Blue Mountains Koala Survey May 2000		Record 20+ years old
5	19/9/98	19/9/98	1	T - Trapped or netted	Caley Crescent, Lapstone Specified Map No: 9030-3-N	100			Record 20+ years old Located on western side of Nepean River
6	30/8/18	30/8/18	0	WR - Wildlife Rehabilitation Record	Suburb only provided: Regentville, 2745	616	Encounter broad: Stranded/Unsuitable environment; Encounter narrow:		Record 3 years old Low level of accuracy (suburb only)

ID	First Date	Last Date	Number of Individuals	Observation	Description	Accuracy	Sighting Notes	Location Notes	Notes
							Unsuitable environment		
7	2/5/00	1/7/00	0	O - Seen		500			Record 20+ years old Located on western side of Nepean River
8	2/6/00	2/6/00	2	O - Seen	Lapstone Specified Map No: 9030	100	Saw 2 Koalas together on median strip of highway, some bush present. At first thought they were possums. Slowed down to have a good look and are positive of ID. Participant in a community Koala survey.		Record 20+ years old Located on western side of Nepean River
9	10/4/18	10/4/18	0	O - Seen	Private property, Shane Park Road, Llandilo, in Palm tree and later Eucalyptus moluccana. Bailed up by domestic dog in yard. WIRES called	100			Record 3.5 years old High level of accuracy Record lies 1.4 km to the north of GPEC
10	17/4/18	17/4/18	0	R - Roadkill	Stony Creek Road, Llandilo south of weir. Killed on road	100			Record 3.5 years old High level of accuracy Record lies 1.7 km to the north of GPEC

ID	First Date	Last Date	Number of Individuals	Observation	Description	Accuracy	Sighting Notes	Location Notes	Notes
11	17/4/18	17/4/18	0	WR - Wildlife Rehabilitation Record	Suburb only provided: Shanes Park, 2760	1669	Encounter broad: Collision; Encounter narrow: Collision - Other		Record 3.5 years old Low level of accuracy. Date may indicate the record is related to animal identified in records 9 and 10? Record lies 1 km to the north of GPEC
12	12/4/06	12/4/06	0	X - In scat	Castlereagh Candidate Area - Eastern section of Colebee Land Specified Map No: 9030-1-S	10		Regenerating upper slope open forest dominated by E. *fibrosa,* with some *E. moluccana.* Moderate tall shrub layer dominated by *Allocasuarina* sp. and *Melaleuca* sp. Few hollows.	Record 15+ years old Scat recorded in an area of woodland in Colebee
13	16/7/90	16/7/90	1	T - Trapped or netted	52 Franklin Crescent, Blackett Specified Map No: 9030-1-S	1000	Specimen seen in tree in backyard. WIRES voucher no. 26517. animal later sent to Coffs Harbour Koala Park. This recording transcribed by Lachlan Laurie via WIRES information supplied by Dr		Record 30+ years old Possibly a north coast record as animal taken to Coffs Harbour Koala Park

							Robert Close, UWSyd.		
14	18/11/16	18/11/16	0	WR - Wildlife Rehabilitation Record	Suburb only provided: Oxley Park, NSW, 2760	636	Encounter broad: Unknown; Encounter narrow: Unknown		Record 5 years old Low level of accuracy (suburb only) Possibly a north coast record as Oxley Park may refer to Port Macquarie (records in western Sydney have been corrected to Port Macquarie in the past)

B. Knowledge-based Method parameters

All candidate SCS not subject to an expert report were assumed present under Section 6.4.1.21 of the BAM, as complete survey to determine species' presence/absence, and/or species' habitat constraints or habitat degradation, was not possible due to the very large size of the project area and associated land access constraints.

Species polygons were developed for all SCS assumed present as required by Section 6.4.1.26 of the BAM, which involved the application of a knowledge-based method (KBM).

Developing species polygons using the knowledge-based method involved the following steps:

a) Creating initial species polygons for each SCS assumed present based on BioNet PCT associations and the project specific vegetation condition states each species was considered likely to occur within (i.e. the vegetation zones within which each species was considered likely to occur, as per Section 6.4.1.30 of the BAM)
b) Additional information about habitat parameters for each species drawn from information in BioNet or published, peer-reviewed literature as prescribed by Section 6.1.1.2 of the BAM was used to refine each species polygon
c) Results of targeted surveys undertaken for the project to further refine several of the species' polygons where the species (or its habitat) was/was not recorded within the mapped areas of habitat

The habitat parameters used in the GIS model to refine the species polygons as part of Step (b) are provided in:

- Section B.1 – Table B-1 shows habitat parameters for species within the nominated areas
- Section B.2 – Table B-2 shows habitat parameters for species outside the nominated areas

The species polygons developed using these parameters are considered to be conservative, suitable to capture impacts to the species habitat using best available data, and appropriate for the scale of the project.

Information about how LiDAR was used in preparing the species polygons is provided at Section B.3.

Please refer to Section 11.5.2 of Chapter 11 for details about the method and approach.

B.1 HABITAT PARAMETERS FOR SPECIES WITHIN THE NOMINATED AREAS

Table B-1: Habitat parameters used in the GIS model to refine species polygons for species within the nominated areas, and justifications for their use

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
Allocasuarina glareicola	BioNet PCT associations: Intact, Thinned	-	-	SOILS: (Blacktown, Agnes Banks, Berkshire Park, Gymea) **Justification:** Existing records occur within these soils	-	-	-	• Removal of Scattered Trees condition state was applied largely to exclude isolated trees throughout suburban areas in GPEC which do not support habitat for the species. It is acknowledged that in doing so there is a small risk that areas of scattered trees in more natural situations (i.e. 'paddock trees'), which may provide potential habitat for the species, were excluded. However, the precautionary nature of mapping all intact and thinned condition vegetation as habitat mitigates the risk that the species' habitat has been under-mapped • The total area of the Scattered Trees condition of associated PCTs in GPEC is 43 ha, of which a single 28 ha polygon occurs on one site that was mapped as such post public submission. This site was surveyed by a BAM accredited assessor and the species was not recorded. Of the remainder, 9.5 ha occurs throughout suburban areas and is not considered habitat for the species • TBDC states 'grows in Castlereagh woodland on lateritic soil'. The soil landscapes selected represent lateritic soils in the assessment area

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								• Soil restriction is justified by SPRAT profile: this species grows on tertiary alluvial gravels, with yellow clayey subsoil and lateritic soil. These soils are low in fertility and are strongly to very strongly acidic… (Matthes, Robertson et al., 1996; Wilson & Johnson, 1989) • The vast majority of associated PCTs occur on these soils, and where suitable habitat spanned the mapped change in soils the species habitat was mapped as present
Callocephalon fimbriatum	BioNet PCT associations: Intact	> 25 ha **Justification:** Medium BAM patch size. Favours old growth forest and woodland attributes for nesting and roosting (OEH, 2019d)	-	-	-	-	Tree height >20 m (CHM) **Justification:** Breeding habitat information (Higgins, 1999b)	• TBDC patch size relates to minimum patch size to be included as a predicted (ecosystem credit) and potential candidate (species credit) species. The habitat model is only looking to map breeding (species credit) habitat, therefore an increase in patch size is justified as the species will forage in much smaller patches than it will breed • Within the assessment area patches of vegetation that could be considered similar to 'old growth forest' would occur in larger patches of vegetation, and as such a medium sized BAM patch size was used to differentiate suitable potential breeding habitat • Higgins (1999a) states: Breeds in hollows, often near water, usually within tall mature sclerophyll forest

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								with dense shrubby understorey, often in secluded valleys, which is not represented by small patches of vegetation in the assessment area • The restriction of trees to 20 m high complements the TBDC requirement for hollows 9m above the ground, as it is not possible to model hollow height, and 10cm hollows do not occur at the top of tree canopies (which is the required parameter to be used in a GIS model)
Calyptorhynchus lathami	BioNet PCT associations: Intact	> 25 ha **Justification:** Medium BAM patch size. Breed in hollows, often near water, usually within tall mature sclerophyll forest with dense shrubby understorey, often in secluded valleys (Higgins, 1999b)	-	-	-	-	Tree height >15 m (CHM) **Justification:** Breeding habitat information (Higgins, 1999b)	• TBDC patch size relates to minimum patch size to be included as a predicted (ecosystem credit) and potential candidate (species credit) species. The habitat model only maps breeding (species credit) habitat, therefore an increase in patch size is justified as the species will forage in much smaller patches than it will breed within • Within the assessment area patches of vegetation that could be considered close to 'secluded' would occur in larger patches of vegetation, as such a medium sized BAM patch size was used to differentiate suitable potential breeding habitat • Garnett, Pedlar et al. (1999) states nest trees on Kangaroo Island were an average of 300 m from the 'habitat edge', which based on a circular area

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								with a 300 m radius equates to a patch of approximately 28 ha • LiDAR was used to refine existing vegetation polygons to trees with canopy over 15m. A 1m buffer was applied to all >15m polygons to increase canopy. These polygons were then merged and used to clip the vegetation polygons to determine suitable habitat. Information on LiDAR is presented below in Section B.3 • Species does not breed in paddock trees, although paddock trees may be essential refuge/stepping-stones. Therefore the removal of Scattered Trees condition form breeding habitat polygons is justified
Cercartetus nanus	BioNet PCT associations: Intact	-	-	-	-	-	-	• Thinned and scattered tree vegetation zones lack an intact shrub layer, and thus the species' preferred food resources • As at 07/07/21 only one record exists for the species within the assessment area (and relates to a WIRES record) despite substantial survey coverage over the past decades. If this species occurs within the assessment area as conservatively assessed it is only likely to occur in the highest quality, undisturbed, intact habitats • Records of the species are heavily skewed towards large intact areas of

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								habitat. For example, nearly 300 records (<20 years old) occur within the drinking water catchment to the east of GMAC. Similar conclusions can be made for other areas where the species has been recorded
Chalinolobus dwyeri	BioNet PCT associations: Intact, Thinned, Scattered Trees	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone')	-	-	Habitat restricted to within a 2000 m buffer on "Cliffline" DEM layer **Justification:** Species roost predominantly in caves and overhangs in sandstone cliffs and forage in nearby high-fertility forest or woodland near watercourses (DERM, 2011)	• Clifflines located in sandstone geologies have been used as the basis for the 2 km habitat buffer. Information on the clifflines DEM layer is presented in Section B.3
Epacris purpurascens	BioNet PCT associations:	-	-	-	-	-	-	• While the species is known to benefit from some disturbance, the Scattered Trees condition state is considered

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
var. *purpurascens*	Intact, Thinned							not to provide suitable habitat for the species
Eucalyptus benthamii	BioNet PCT associations: Intact, Thinned, Scattered Trees	-	Habitat restricted to within a 350 m buffer of the 'NEPEAN RIVER' Hydro Area **Justification:** Requires a combination of deep alluvial sands and a flooding regime to recruit seedlings (OEH, 2019d) and captures extent of species records	ROCK UNIT: ('Alluvium', 'Bringelly Shale', 'Hawkesbury Sandstone')	Between 25 to 300 m (OEH, 2019d)	-	-	• The assessment area in the vicinity of certified land does not support the species' characteristic riverbank and alluvial floodplain habitat (required to facilitate seedling recruitment) • Certified land occurs within 800 m of Mulgoa Creek and a species record; however the certified land occurs 30-40 m higher in elevation than the watercourse, and vegetation in that area is mapped as PCT 850, illustrating the non-floodplain nature of the habitat • Certified land occurs near Manangle Park but this is over 1.5km from the watercourse and is surrounded by unsuitable PCT 850 habitat • A 350 m buffer was determined as appropriate through numerous iterations of the habitat model and is considered suitable to represent an area supporting 'a combination of deep alluvial sands and a flooding regime to recruit seedlings' • It is acknowledged that BioNet records do not represent complete presence/absence data for the species, however the 763 records dataset represents best available information and its use is considered appropriate

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
Grevillea parviflora subsp. *Parviflora*	BioNet PCT associations: Intact, Thinned	-	-	SOILS: ('Berkshire Park', 'Lucas Heights', ' Wianamatta (South Creek) ROCK UNIT: ('Alluvial channel deposits- in-channel bar', 'Alluvial floodplain deposits', 'Alluvium', 'Mittagong Formation', 'Alluvial terrace deposits') **Justification:** Sydney region occurrences are usually on Tertiary sands and alluvium, and soils derived from the Mittagong Formation. Soil landscapes include Lucas Heights or	Between 25 to 300 m (OEH, 2019d)	-	-	• TBDC notes the species o*ften occurs in open, slightly disturbed sites such as along tracks*. Scattered trees vegetation zones are highly disturbed (and often not representing 'paddock trees') and this condition state is not therefore considered to provide suitable habitat for the species • TBDC states that Sydney region occurrences of the species are usually on Tertiary sands and alluvium, and soils derived from the Mittagong Formation. Soil landscapes include Lucas Heights or Berkshire Park. The soil / geology restriction applied is based on interpretation of information in the TBDC to model the species transitional soil habitat requirements in a way that can be used in a GIS habitat model • It is acknowledged that BioNet records do not represent complete presence/absence data for the species, however the >1400 records dataset (within the vicinity of the assessment area) represents best available information and its application and use is considered appropriate

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
				Berkshire Park (OEH, 2020c) Habitat also present where PCTs occur on or within 200 m of Hawkesbury soils AND sandstone geology (Hawkesbury Sandstone) (i.e. must satisfy both criteria) **Justification:** at least 80 of the 97 records of the species that occur outside Lucas Heights soils (around Wilton and GMAC) meet the above criteria				
Haliaeetus leucogaster	BioNet PCT associations: Intact	>5 ha **Justification:** Exclude small, isolated patches of vegetation	Habitat restricted to within 350 m around Strahler order >3 or any waterbody including hydronametype IN	-	-	-	-	• TBDC patch size relates to minimum patch size to be included as a predicted (ecosystem credit) and potential candidate (species credit) species. The habitat model only maps breeding (species credit) habitat, therefore an increase in patch size is justified as the species

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
		from habitat model	('BRANCH', 'DAM', 'LAKE', 'LAKES', 'RESERVOIR', 'RIVER', 'ARM') **Justification:** Selection of nest site data (Dennis, McIntosh et al., 2011)					will forage in much smaller patches than it will breed within • Dennis, McIntosh et al. (2011) is used to justify an appropriate buffer from watercourses. The study notes all but one nest (~350 m) was within 250 m of the coastline. This data in combination with Debus (2008), which states the nests monitored in that study were all within 425 m of a watercourse, was used to derive 350 m as a realistic breeding habitat buffer in the context of the assessment area • TBDC breeding constraint refers to living or dead mature trees within suitable vegetation within 1km of rivers, lakes, large dams or creeks, wetlands and coastlines. Paddock trees are not considered important for breeding, but for essential refuge/stepping stones. Therefore, the removal of the Scattered Trees condition state from breeding habitat polygons is considered justified • No wetlands were excluded based on the GIS selection of waterbodies. 'Coastal areas' do not occur within or near the assessment area
Heleioporus australiacus	BioNet PCT associations: Intact	>5 ha **Justification:** Exclude small,	Habitat restricted to within 300 m of 1st, 2nd, and 3rd order	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury	-	-	-	• Breeding habitat is generally soaks or pools within first or second order streams, and the species spends more than 95% of its time in non-

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
		isolated patches of vegetation from habitat model	watercourses, excluding overlapping areas within 300 m from a 4th (or higher) order watercourse **Justification:** Burrows in the creek bank. Eggs are laid in burrows or under vegetation in small pools. Breeding habitat is generally soaks or pools within first or second order streams. (up to 300 metres from breeding site (first and second order streams) (OEH, 2019d)	Sandstone'), and SOILS: NOT in ('Blacktown', 'Glenorie', 'Luddenham', 'Picton', 'West Pennant Hills') **Justification:** Found in vegetation on a variety of soil types except those that are clay based (OEH, 2019d)				breeding habitat in areas up to 300 m from breeding sites • Areas within 300m of 4th or higher watercourses associated with non-clay-based soils within the assessment area represent steep slopes not characteristic of the species preferred habitat of 'small slow flowing clear water courses, broad upland gullies, stream headwaters and permanently moist soaks and pondages' (NPWS, 2001) • No certified land occurs within 300 m of >4th order streams, no dams occur within suitable vegetation, no other waterbodies are relevant • Soil restrictions represent non-clay soils within the assessment area

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
Hieraaetus morphnoides	BioNet PCT associations: Intact, Thinned	>5 ha **Justification:** Excludes small, isolated patches of vegetation as habitat	-	-	-	Habitat excluded from within 215 m of a dwelling and 65 m from industrial building **Justification:** Little Eagle expert report for WGA and GMAC (Saunders & Debus, 2018)	Minimum tree height restricted to 20m **Justification:** Nest trees height determined in WSA and GMAC expert report (Saunders & Debus, 2018)	• Relevant parameters detailed in the export report prepared for Wilton and GMAC have been used in the preparation of this habitat model • It is acknowledged that the expert report states the 'species will nest in tall living eucalypts between 5 and 30 m tall in open forest, woodland, and remnant woodland in farmland', however this is considered to be background context. The expert report sets out minimum nesting requirements in Table 1 and 2 of the report, which identify setbacks from development and minimum criteria for nest site characteristics. The report states 'the minimum nesting requirements for Canberra in Table 1 are more relevant to this study'. Table 1 was used for setbacks from development, Table 2 was used for nest tree height • TBDC patch size relates to minimum patch size to be included as a predicted (ecosystem credit) and potential candidate (species credit) species. The habitat model only maps breeding (species credit) habitat, therefore an increase in patch size is justified as species will forage in much smaller patches than it will breed within • The expert report states nests are typically in an emergent eucalypt,

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								the tallest in the stand and often with the largest girth, in woodland patches at least 4.8 ha in size (average 85 ha). This 4.8 ha criteria was rounded up to 5 ha, but is still well below the average size noted in the report • It is acknowledged that the TBDC states 'paddock trees can provide important breeding habitat', however this is considered to be a generic statement relevant to the species' range across all of NSW and is not supported by the expert report prepared for the assessment area. Therefore, the removal of the Scattered Trees condition state from breeding habitat polygons is considered justified
Lophoictinia isura	BioNet PCT associations: Intact	>5 ha **Justification:** Exclude small, isolated patches of vegetation from habitat model	Habitat restricted to within 350 m around Strahler order 3+ watercourses or any waterbody including hydronametype IN ('BRANCH', 'DAM', 'LAKE', 'LAKES', 'RESERVOIR', 'RIVER', 'ARM')	-	-	-	-	• TBDC patch size relates to minimum patch size to be included as a predicted (ecosystem credit) and potential candidate (species credit) species. The habitat model only maps breeding (species credit) habitat, therefore an increase in patch size is justified as species will forage in much smaller patches than it will breed within • Furthermore Table 2 of the expert report states the minimum requirement for forest/woodland patch size is 5 ha and 'in fragmented

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
			Justification: Species shows a particular preference for timbered watercourses, with nest sites generally located along or near watercourses (OEH, 2019d)					landscapes with much larger patches nearby' • 'Timbered watercourses' present within GPEC and WSA are generally represented by Strahler order 3+ watercourses. While there are a limited number of 2nd order streams in Orchard Hills and Wianamatta Regional Park, these areas not to be certified • A 350 m setback was developed through the iterative development of the GIS model process and with reference to the habitat requirements outlined in the expert report
Marsdenia viridiflora subsp. *viridiflora - endangered population*	BioNet PCT associations: Intact, Thinned	-	-	-	-	LGAs IN ('BANKSTOWN','BLACKTOWN', 'CAMDEN', 'CAMPBELLTOWN', 'FAIRFIELD', 'HOLROYD', 'LIVERPOOL', 'PENRITH')	-	• Removal of Scattered Trees condition state was applied largely to exclude isolated trees throughout suburban areas in GPEC which do not support habitat for the species. It is acknowledged that in doing so there is a small risk that areas of scattered trees in more natural situations (i.e. 'paddock trees'), that do provide potential habitat for the species were excluded, but the precautionary nature of mapping all intact and thinned condition vegetation as habitat mitigates the risk that the species' habitat has been under-mapped. It is considered that inclusion of Scattered Trees would have over-mapped the species' habitat by approximately 120 ha

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
Maundia triglochinoides	BioNet PCT associations: Intact, Thinned	-		SOILS: (Berkshire Park, Birrong, Blacktown, Deep Creek, Freemans Reach, Glenorie, Lane Cove, Monkey Creek, Picton, Richmond, Wianamatta (South Creek), Teresa Park, Upper Castlereagh) **Justification:** Grows on heavy clay (OEH, 2019d)	-	-	-	• The soils restriction is considered to be consistent with information in the TBDC that says the species "Grows in swamps, lagoons, dams, channels, creeks or shallow freshwater 30 - 60 cm deep on heavy clay, low nutrients" • The GIS model accounts for potential unpredictability by applying broad parameters around PCT and soil associations only, and is considered to be conservative and likely to map all areas of potential habitat
Micromyrtus minutiflora	BioNet PCT associations: Intact, Thinned	-	-	-	Up to 50 m (Doug & Lyn, 1998)	-	-	• A review of an as-held BioNet extract from 07/07/21 shows all records within, and to the north of, the assessment area occurring at ~50 m elevation or less (470 of the total 472 BioNet records), with records in the Richmond area generally siting at around 20 m elevation • It is acknowledged that two records of the species occur at higher elevations near Fairlight Rd, Mulgoa, however these were considered outliers, and the published literature referenced, combined with 99.5% of

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								BioNet records, were considered suitable to support the use of elevation as a habitat parameter • Removal of Scattered Trees condition state was applied largely to exclude isolated trees throughout suburban areas in GPEC which do not support habitat for the species. It is acknowledged that in doing so there is a small risk that areas of Scattered Trees in more natural situations (i.e. 'paddock trees'), that do provide potential habitat for the species were excluded, but the precautionary nature of mapping all intact and thinned condition vegetation as habitat mitigates the risk that the species' habitat has been under-mapped
Myotis macropus	BioNet PCT associations: Intact, Thinned, Scattered Trees	-	All waterbodies in the Plan Area with pools/reaches of water 3 m or wider and areas of habitat within 200 m of these waterbodies where they coincide with the relevant PCTs (OEH, 2019d)	-	-	-	-	• Species polygon prepared in accordance with 'Species credit' threatened bats and their habitats NSW survey guide for the Biodiversity Assessment Method (OEH, 2018i)

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
Ninox connivens	BioNet PCT associations: Intact	>25 ha **Justification:** Moderate BAM patch size, removes isolated patches	Restricted to within 100 m of a watercourse **Justification:** Breeding habitat known to be similar and more restrictive than Powerful Owl (DEC, 2006)	-	-	-	Vegetation within "Gullies" DEM layer **Justification:** Breeding habitat known to be similar and more restrictive than Powerful Owl (DEC, 2006)	• The species typically breeds in hollows of large eucalypts or paperbarks, usually near watercourses or wetlands (NSW NPWS, 2003b). The species appears most abundant in the largest remnants but also occurs at low density in fragmented habitat, where it uses healthy riparian woodland or gallery forest amid extensive, diverse woodland supporting a diversity of native prey (Debus, 2001). Sometimes able to successfully breed along timbered watercourses in heavily cleared habitats (e.g. western NSW) due to the higher density of prey found on these fertile riparian soils (DPIE, 2021). Barking Owl habitat has a strong spatial association with hydrological features such as rivers and wetlands (Kirsten & Taylor, 1999) • Information on the DEM "gullies" layer is provided in Section B.3. The layer was able to accurately map the occurrence of gullies and a GIS process was then used to capture those gullies that occur within 100m of mapped watercourses • Species use of paddock trees considered to be for essential refuge/stepping stones, not breeding. Therefore, the removal of the Scattered Trees condition state from

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								breeding habitat polygons is considered justified
Ninox strenua	'BioNet PCT associations: Intact'	-	Restricted to within 100 m of a watercourse **Justification:** Nests in old hollow eucalypts in unlogged, unburnt gullies and lower slopes within 100 m of streams or minor drainage lines (DEC, 2006)	-	-	-	Vegetation within "Gullies" DEM layer **Justification:** Nests in old hollow eucalypts in unlogged, unburnt gullies and lower slopes within 100 m of streams or minor drainage lines (DEC, 2006)	• (DEC, 2006) states the species breeds in hollow eucalypts in unlogged, unburnt gullies. The Intact vegetation condition is considered to represent this requirement • Information on the DEM "gullies" layer is provided in Section B.3
Persicaria elatior	BioNet PCT associations: Intact, Thinned, Scattered Trees, DNG	-	Habitat mapped within vegetation polygons occurring within 50m of the following hydro areas: Anabranch, Backwater, Billabong,	SOILS: ('Wianamatta (South Creek), 'Richmond', 'Freemans Reach', 'Berkshire Park', 'Upper Castlereagh)	-	-	-	• No condition restriction has been applied, so when combined with associated PCTs, proximity to waterbodies and sandy/alluvial soil restriction (based on soils occurring in the assessment area) the habitat model reflects the requirements as listed in the TBDC and publish information on the species

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
			Branch, Cowal, Creek, Pond, River, Stream, Swamp, Watercourse, Waterway **Justification:** Species grows in damp places, especially beside streams and lakes, occasionally in swamp forest (OEH, 2019d)	**Justification:** Species grows on sandy, alluvial soil (DEWHA, 2008c)				• 'Hydro layer' refers to the NSW Water Theme of the Foundation Spatial Data Framework (FSDF) - Hydro Line © Spatial Services 2021 and NSW Water Theme of the Foundation Spatial Data Framework (FSDF) – Hydro Area © Spatial Services 2021. This is part of the LPI set of topography spatial layers
Persoonia bargoensis	BioNet PCT associations: Intact, Thinned	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member') AND Blacktown, Glenorie, Picton, Luddenham soil landscapes within 80 m of the edge of the	0 - 450 m **Justification:** As detailed in Cunninghamia Vol. 6(4): 2000, increased based on records around Bargo (Doug & Lyn, 1998)	-	-	• Soil restrictions as detailed were those relevant to the assessment area and were used to constrain the GIS model to map habitat in the area of transition between/surrounding mapped soil types (as referred to in the TBDC). This restriction was necessary due to the species being associated with several PCTs that occur away from this transitional zone (as well as on/near it), PCT 849 for example. The restriction of 80 m was selected as a result of multiple iterations of the model outputs • It is acknowledged that the TBDC states the 'species seems to benefit from the reduced competition and increased light available on disturbance margins including

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
				sandstone geology **Justification:** Species favours interface soil landscapes such as between the Blacktown Soil Landscape and the complex Mittagong Formation soils (Lucas Heights Soil Landscape) with the underlying sandstone (OEH, 2019d)				roadsides'. This is considered to represent the level of disturbance present within the Thinned condition state not the Scattered Trees condition state. The Scattered Trees condition state vegetation has generally undergone significant historical and/or ongoing disturbance such as urbanisation, slashing, grazing and other farming activities, which is considered more intensive than disturbance that occurs on roadside margins. Furthermore, repeated slashing of roadside margins would prevent the species' seedbank establishment (NPWS, 2000) • It is expected that the TBDC noting Paddock Trees as important to the species is likely to reflect the species tolerance to some disturbance, however substantial and/or ongoing disturbance will negatively impact upon the species occurrence, and this level is considered to be occurring within Scattered Trees condition vegetation
Petaurus norfolcensis	BioNet PCT associations: Intact, Thinned, Scattered Trees	>4 ha **Justification:** Expected home range within the Plan Area	-	-	-	-	Vegetation 10 m tall and higher, buffer all polygons by 12.5 m (to establish	• The assessment area is considered a 'coastal area' and not an 'inland forest fragment'; and as such a home range of 4 ha is considered appropriate to select suitable connected vegetation

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
		(NSWSC, 2008)					connected habitat within glide ratio of 1:2.5 for 10 m trees), clip the buffered polygons back to vegetation polygons, select patches that are 4 hectares and greater **Justification:** Connected habitats are those which the animals can reach by gliding, 10m tall trees are the minimum expected height for glide launch (Jackson, 2000; Vernes, 2001)	• NSWSC (2008) notes Squirrel Gliders have limited ability to disperse across urban or agricultural land. Although capable and willing to cross open habitat on occasion (e.g. to reach heavily flowering trees), they more typically require sufficient connectivity of tree cover within their maximum gliding distance (70 m: (Van der Ree, 2002; Van der Ree, Bennet et al., 2003)). They are therefore susceptible to habitat fragmentation and hence population fragmentation. Based on this the model parameter of connected habitat being patches separated by 25 m (12.5 m buffer surrounding polygons) is consider highly conservative • LiDAR was used to select >10m height polygons within associated PCTs. These polygons were then buffered by 12.5 m to select all 'connected' vegetation polygons within 25 m of each other. Buffered polygons were then merged and used to clip the original vegetation mapping polygons. If the resultant clipped vegetation polygons were part of a >4 ha patch, the patch was mapped as habitat for the species. The buffering allows for areas of vegetation <10m in height to be captured in the species polygons and

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								captures the species ability to "run short distances across open ground"
Pimelea curviflora var. *curviflora*	BioNet PCT associations: Intact, Thinned	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone') AND All Blacktown soil landscape within a 500m buffer on Wianamatta (South Creek), plus all Berkshire Park soil landscape **Justification:** Occurs on shaley/lateritic soils over sandstone and shale/sandstone transition soils (OEH, 2019af)	Less than 300 m (Doug & Lyn, 2001)	-	Sandstone units selected only within a 100 m buffer on "Ridge and Crest" DEM layer **Justification:** Occurs on shale/sandstone transition soils on ridgetops and upper slopes amongst woodlands (OEH, 2019d)	• TBDC states that the species occurs on 'shale/sandstone transition soils on ridgetops and upper slopes amongst woodlands geology'. Soil and DEM layers have been used to constrain the GIS model to map habitat in the area of transition between/surrounding mapped soil types (as referred to in the TBDC). This restriction was necessary due to the species being associated with several PCTs that occur away from this transitional zone (as well as on/near it), for example PCT 849. The restriction of 80 m was selected as a result of multiple iterations of the model outputs • Removal of Scattered Trees condition state was applied largely to exclude isolated trees throughout suburban areas in GPEC which do not support habitat for the species. It is acknowledged that in doing so there is a small risk that areas of scattered trees in more natural situations (i.e. 'paddock trees'), that do provide potential habitat for the species were excluded, but the precautionary nature of mapping all

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								intact and thinned condition vegetation as habitat mitigates the risk that the species' habitat has been under-mapped. It is considered that inclusion of Scattered Trees would have over-mapped the species' habitat by approximately 100 ha • Note that the DEM layer and 'sandstone units' was ultimately not applied as the species was removed as a candidate from Wilton and GMAC
Pomaderris brunnea	BioNet PCT associations: Intact, Thinned	-	100 m around waterways **Justification:** Grows in moist woodland or forest on clay and alluvial soils of flood plains and creek lines (OEH, 2019d)	SOILS: ('Blacktown', 'Lucas Heights') **Justification:** Grows in moist woodland or forest on clay and alluvial soils of flood plains and creek lines (OEH, 2019d)	Up to 450 m (BioNet records)	-	-	• It is considered that the 100m around waterways restriction represents the 'moist woodland or forest on clay and alluvial soils of flood plains and creek lines' within the assessment area • Elevation justification is confirmed as appropriate by (Benson & McDougall, 2000) • Following a review of available literature, it was concluded that intact and thinned condition state PCTs were most representative of the species' potential habitat within the assessment area
Pseudophryne australis	BioNet PCT associations: Intact	-	Restricted to 1st and 2nd order watercourses (OEH, 2019d)	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone')	-	-	Habitat buffered to 50m above and 100m below "Ridge and	• Habitat restricted to 100m from 1st and 2nd order watercourses, where those watercourses occur in association with the stated geologies as mapped in NSW Seamless Surface

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
				inside Ridge and Crest **Justification:** Occurs in open forests, mostly on Hawkesbury and Narrabeen Sandstones (OEH, 2019d)			Crest" DEM layer **Justification:** Species usually restricted to within 100 m of a ridgetop (NPWS, 2001)	Geology Rock Units (Colquhoun, Hughes et al., 2020) • DEM layer (information is detailed in Section B.3.) was used to refine habitat to within 50-100m of ridgetops as outlined in (NPWS, 2001)
Pultenaea parviflora	BioNet PCT associations: Intact, Thinned	-	-	-	Less than 120 m (Doug & Lyn, 1996)	-	-	• Elevation criteria is taken from published literature (Doug & Lyn, 1996). Furthermore, all BioNet records of the species with and proximal to the assessment area occur well below 120 m, with most occurring below 70 m • It is acknowledged that BioNet records do not represent complete presence/absence data for the species, however the ~1,000 records dataset (proximal to the assessment area) represents best available information and its application and use in this instance is considered appropriate • Removal of Scattered Trees condition state was applied largely to exclude isolated trees throughout suburban areas in GPEC which do not support habitat for the species. It is acknowledged that in doing so there is a small risk that areas of scattered trees in more natural

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
								situations i.e. ('paddock trees'), that do provide potential habitat for the species were excluded, but the precautionary nature of mapping all intact and thinned condition vegetation as habitat mitigates the risk that the species' habitat has been under-mapped
Pultenaea pedunculata	BioNet PCT associations: Intact, Thinned, Scattered Trees	-	-	Occurs on Blacktown, Wianamatta (South Creek), Berkshire Park soil landscapes AND On, or within a 600 m buffer from, "Alluvium" in "GRPSUITE" field OR Within 500 m buffer from boundaries sandstone derived soil landscapes **Justification:** Favours sites in clay or sandy-clay soils on Wianamatta Shale-derived	Less than 150 m (Doug & Lyn, 1996)	-	-	• Soil restrictions as detailed were those relevant to the assessment area. They were used to constrain the GIS model to map habitat in the area of clay or sandy-clay soils on Wianamatta Shale-derived soils, usually close to patches of Tertiary Alluvium, or at or near the Shale-Sandstone interface, with all sites having a lateritic influence (as referred to in the TBDC). Buffers of 500 m and 600 m were used based on multiple iterations of the GIS model process and were determined to best represent the species habitat. This restriction was necessary due to the species being associated with several PCTs that occur away from these soil transitional zones (as well as on/near it), for example PCT 849 and 850 • "GRPSUITE" field relates to in NSW Seamless Surface Geology Rock Units (refer to reference above) • Sandstone derived soil landscapes include: Faulconbridge, Gymea, Gymea/Lambert, Hawkesbury,

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
				soils, usually close to patches of Tertiary Alluvium, or at or near the Shale-Sandstone interface. All sites have a lateritic influence (OEH, 2019d)				Lambert, Oxford Falls (incl. Var a and Var. b) soil landscapes • Including Intact, Thinned, Scattered Trees vegetation conditions is considered appropriate based on the statement in the TBDC that the species is a good coloniser of bare ground. The only condition excluded from the GIS model is DNG which is not considered to represent the 'bare ground' habitat referred to in the TBDC descriptions. Coloniser of bare ground relates to disturbed edges such as those surrounding Thinned and Scattered tree condition vegetation. Where DNG may occur immediately adjacent to these areas the plant has some potential to occur, however the assumption of presence across all other condition states is considered to result in conservative species polygons
Tyto novaehollandiae	Intact, Thinned	All "Intact" Vegetation or "Thinned" patches over 10 ha in area **Justification:** Removed scattered and isolated occurrences of 'Thinned' vegetation	-	-	-	-	Vegetation within "Gullies" DEM layer **Justification:** Roosts and breeds in moist eucalypt forested gullies, using large	• DEM "gullies" layer has been used to map suitable breeding habitat for the species within the project area. • TBDC patch size relates to minimum patch size to be included as a predicted (ecosystem credit) and potential candidate (species credit) species, across the species entire NSW range. The habitat model is only looking to map breeding (species credit) habitat within the project area, therefore an increase in

Scientific name	Vegetation condition	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	LiDAR	Further comments to justify parameters used to prepare species polygons
		not suitable for breeding habitat					tree hollows or sometimes caves for nesting (OEH, 2019d)	patch size to captured potential breeding habitat within 'Thinned' condition vegetation was required to map suitable habitat patches and is considered justified. • The inclusion of Intact and Thinned condition vegetation accounts for the species' (DEC, 2006)

B.2 HABITAT PARAMETERS FOR SPECIES OUTSIDE THE NOMINATED AREAS

Table B-2: Habitat parameters used in the GIS model to refine habitat mapping for species outside the nominated areas within the Cumberland subregion

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
Allocasuarina glareicola	Intact, thinned	BioNet PCT associations	>40 ha **Justification:** Exclusion of small patches of vegetation not meeting the known geographic extent of the species	-	-	Below 50 metres (Doug & Lyn, 1995)	Primarily restricted to the Richmond (NW Cumberland Plain) district, but with an outlier population found at Voyager Point, Liverpool (DAWE, 2020)	>800 mm (Doug & Lyn, 1995)
Anthochaera phrygia	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	-	-	-	-	-
Botaurus poiciloptilus	Intact, thinned	BioNet PCT associations	-	40 m buffer applied to hydrolines **Justification:** Preferred habitat is comprised of wetlands, often at the edges of pools or waterways, or from platforms or mats of vegetation over deep water (DAWE, 2020).	-	-	-	-

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
Chalinolobus dwyeri	Intact, thinned	BioNet PCT associations	-	-	Habitat restricted to within 2 kms of Rock Units ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member') **Justification:** species primarily roosts in caves and overhangs in sandstone cliffs and forage in nearby high-fertility forest or woodland near watercourses (DECC, 2007; Pennay, 2008; Pennay & Gosper, 2002)	-	-	-

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations

Hoplocephalus bungaroides	Intact	BioNet PCT associations	>5 ha **Justification:** Excluded small, isolated patches of vegetation from habitat model	-	-	-	-	-
Lathamus discolor	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	-	-	-	-	-
Leucopogon exolasius	Intact, thinned	BioNet PCT associations	-	200 m buffer applied to Cataract River and Georges River: **Justification:** Restrict to known area of occurrence of the species, and the species' inhabits woodland on sandstone (and sandy alluvium) and prefers rocky hillsides along creek banks - prefers rocky hillsides along creek	SOILS: ('Berkshire Park', 'Freemans Reach', 'Hawkesbury', 'Monkey Creek', 'Richmond', Wianamatta (South Creek), 'Theresa Park', 'Upper Castlereagh') ROCK UNIT: ('Alluvial channel deposits- in-channel bar', 'Alluvial floodplain deposits',	Below 400 metres (DAWE, 2020)	-	1000-1400 mm (DAWE, 2020)

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
				banks (DAWE, 2020).	'Alluvial terrace deposits', 'Alluvium', 'Hawkesbury Sandstone', 'Minchinbury Sandstone') **Justification:** Sandstone and sandy alluvium (DAWE, 2020).			
Macquaria australasica	-	N/A	-	The waterways identified in the recovery plan (DoEE & DPI, 2018) that occur within and close to the Strategic Assessment Area that support self-sustaining native populations, or translocated and stocked populations Any additional waterways within the Strategic Assessment Area that support records of the species since 2000	-	-	-	-

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
Melaleuca deanei	Intact, thinned	BioNet PCT associations	-	-	-	Below 400 metres (DAWE, 2020)	-	1000-1400 mm (DAWE, 2020)
Persicaria elatior	All	BioNet PCT associations	-	Habitat mapped within vegetation polygons occurring within 50m of the following HydroAreas: Anabranch, Backwater, Billabong, Branch, Cowal, Creek, Pond, River, Stream, Swamp, Watercourse, Waterway **Justification:** Species grows in damp places, especially beside streams and lakes, occasionally in swamp forest (OEH, 2020d)	-	-	-	-
Persoonia glaucescens	Intact, thinned	BioNet PCT associations	-	-	-	250-650m (DAWE, 2020)	Restricted to within 7.5 kms of existing records	-

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
Petauroides volans	Intact	BioNet PCT associations	>25 ha **Justification:** Restrict habitat to larger areas of vegetation. BioNet notes species can occur in medium patches of 5-24ha, however this was returning many unsuitable areas as habitat	-	-	-	-	-
Pimelea curviflora var. *curviflora*	Intact, thinned	BioNet PCT associations	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member') AND All Blacktown soil landscape within a 500 m buffer on Wianamatta (South Creek) plus all	Below 300 metres (DAWE, 2020)	-	-

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
					Berkshire Park soil landscape **Justification:** Occurs on shaley/lateritic soils over sandstone and shale/sandstone transition soils (OEH, 2019d)			
Pterostylis saxicola	Intact	BioNet PCT associations	-	-	Include 'Lucas Heights', 'Woodlands' with ROCK UNIT: ('Hawkesbury Sandstone', 'Ashfield Shale', 'Mittagong Formation' **Justification:** Ashfield Shale, Mittagong Formation shales and sandstones, and Hawkesbury Sandstone and Devonian metasediments (DAWE, 2020)	-	-	<300 mm (DAWE, 2020)

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
Rostratula australis	Intact	Vegetation classes derived from DAWE (DoE, 2015b)	-	All waterways (hydrolines) that have hydronames or group/sub-group types as below with 40m buffer from that watercourse This includes 'Coastal lagoons and lakes', 'Estuarine Wetland', 'Floodplain Wetland', 'Freshwater Lake', 'Reservoir', 'Saline Wetland') And SUBGROUP Coastal vegetation', 'Named coastal lagoons and lakes', 'Unnamed coastal lagoons and lakes', 'Estuarine water body', 'Floodplain water body', 'Named freshwater lake',	-	-	-	-

Scientific name	Vegetation condition	Vegetation associations	Patch size	Waterways	Soil/geology restrictions	Elevation	Geographic	Rainfall associations
				'Unnamed freshwater lake', 'Canal', 'Dam', 'Golf Course', 'Quarry', 'Reservoir', 'Sewage Treatment Pond', 'Saline Lake' **Justification:** Wetland habitats as detailed in SPRAT profile (DAWE, 2020)				

B.3 INFORMATON ON LIDAR PROCESSING

A number of data layers (derived sub-models) were produced using LiDAR for use in preparation of the species polygons. This section:

- Sets out the LiDAR metadata
- Describes the processing steps to create the following LiDAR derived sub-models:
  - Ridge and crest layer
  - Gullies layer
  - Cliff lines layer

B.3.1 LIDAR METADATA

Source: A Division of Department of Finance, Services and Innovation - PENRITH, 2kmx2km Point Cloud Metadata (https://s3-ap-southeast-2.amazonaws.com/nsw.elvis/z56/Metadata/Penrith201102-LID1-C3-AHD_2826250_56_0002_0002_Metadata.html#)

Abstract: The coverage of this dataset is over the PENRITH region. Data of this specification (Spatial Services Category 1 LiDAR) contains point data in LAS format sourced from a LiDAR (Light Detection and Ranging) ALS50 (SN101) sensor. The processed data has been manually edited to achieve ICSM Classification Level 3 whereby the ground class contains minimal non-ground points such as vegetation, water, bridges, temporary features, jetties etc. This data has an accuracy of 0.3m (95% Confidence Interval) vertical and 0.8m (95% Confidence Interval) horizontal with a minimum point density of 1.05 points per square metre. For more information on the data accuracy, refer to the lineage provided in the data history.

Purpose: To provide fit-for-purpose elevation data for use in applications related to coastal vulnerability assessment, natural resource management (especially water and forests), transportation and urban planning.

Topic Category: location, elevation, geoscientific information.

Acquisition Start Date: 2011-02-24

Acquisition End Date: 2011-02-24

Spatial Accuracy Horizontal: +/-0.80@95% Confidence Interval

Spatial Accuracy Vertical: +/-0.30 @95% Confidence Interval

B.3.2 LIDAR DERIVED SUB-MODELS

RIDGE AND CREST LAYER

Purpose

To create polygons representing the Ridged and Crest features in the nominated areas using LiDAR data for use in KBM models. A number of specific values and parameters were developed through numerous iterations of the output layers.

Dependencies

Create DEM and CHM

Method

Step	Tool	Parameters	Justification
Create focal mean raster	Focal Statistics	Stat: Mean Neighbourhood 30x30	Focal mean shows the average change in elevation within the neighbourhood with higher values representing areas that above the neighbourhood average and will typically represent local high spots.

			Testing on several different neighbourhood sizes indicated the 30x30 cells (30mx30m) produced the best results.
Create Topographic Position Index (TPI)	Raster Calculator	Focal Mean minus DEM	Subtracting the DEM value from the focal mean values returns a surface that shows how far above or below the local average each location is.
Convert to binary	Reclassify	Classes: -100-1, No data, 1-100, 1	Comparing different breakpoints to the aerial imagery, 1m change over a 30x30 area was selected as the best fit.
Buffer by 5	Expand	Expand Value 5:	Buffers the features to close small gaps and narrow features to create more linear features.
Convert to polygons	Raster to polygon	Simplify: No	

GULLIES LAYER

Purpose

To create polygons representing the upper slopes and crests of gullies in the in the nominated areas using LiDAR data for use in KBM models. A number of specific values and parameters were developed through numerous iterations of the output layers.

Dependencies

Create DEM and CHM

Method

Step	Tool	Parameters	Justification
Create focal range raster	Focal Statistics	Stat: Range Neighbourhood 5x5	Focal range shows the maximum change in elevation within the neighbourhood with higher values representing cliffed areas. Testing on several different neighbourhood sizes indicated the 5x5 cells (5mx5m) produced the best results.
Convert to binary	Reclassify	Classes: -100-2, No data, 2-100, 1	Comparing different breakpoints to the aerial imagery, 2m change over a 5x5 area was selected as the best fit.
Convert to polygons	Raster to polygon	Simplify: No	
Select crests relating to gullies	Select layer by location	Within 5m of LPI Hydroline	Any cell with a change of greater than 2m with a 5x5m neighbourhood.
Merge adjacent polygons to create linear shapes	Buffer	Buffer by 5m and dissolve Buffer by -5m to retain joins by remove areas on outsides	
Intersect with vegetation zones	Intersect	Input layers: consolidated vegetation	To remove any polygons that do not fall within potential habitat.

		Gully candidates	

CLIFF LINES LAYER

Purpose

To create polygons representing likely cliff lines in the in the nominated areas using LiDAR data for use in KBM models. A number of specific values and parameters were developed through numerous iterations of the output layers.

Dependencies

Create DEM and CHM

Method

Step	Tool	Parameters	Justification
Create focal range raster	Focal Statistics	Stat: Range Neighbourhood 5x5	Focal range shows the maximum change in elevation within the neighbourhood with higher values representing cliffed areas Testing on several different neighbourhood sizes indicated the 5x5 cells (5mx5m) produced the best results.
Convert to binary	Reclassify	Classes: 0-8, No data, 8-100, 1	Comparing different breakpoints to the LPI topo DLS layer indicated that an 8m change over a 5x5 area was the best fit.
Convert to polygons	Raster to polygon	Simplify: No	

C. Biological and important populations definitions

Assumptions made in defining biological populations and identifying important populations for each Commonwealth-listed Category 1 species within the Strategic Assessment are provided in Table C-1. See Section 11.5.3 in Part 3 for context.

Table C-1: Biological populations and important populations definitions

Scientific Name	Cth status	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Acacia bynoeana	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Limited information is available on the dispersal distance of *A. bynoeana* The recovery plan for *A. pubescens* notes that dispersal over a distance of 300 m is considered likely for *Acacia* spp. (NSW NPWS, 2003a) Therefore, plants within 300 m of each other have been defined as one population	Populations of *A. bynoeana* were considered important because they met one or more of the following criteria: • A large population • A population within a conservation area • A population that is site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
Acacia pubescens	Vulnerable	All available BioNet records were used to identify populations, with no date restrictions	Plants within 300 m of each other have been defined as one population, as dispersal is considered likely to occur over this distance in *Acacia* spp. (NSW NPWS, 2003a)	Populations of *A. pubescens* were considered important because they met one or more of the following criteria: • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program • A large population • Is associated with a commitment made under the Sydney Growth Centres conservation program • A population within a conservation area
Allocasuarina glareicola	Endangered	All available BioNet records were used to identify populations, with no date restrictions	Biological populations were defined based on clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollination	All populations of *A. glareicola* were considered important as the species is endangered
Anthochaera phrygia	Critically Endangered	All available BioNet records were considered in the assessment	The Regent Honeyeater comprises a single population (DoE, 2016b)	The population was considered to be important as the species is critically endangered

Scientific Name	Cth status	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Botaurus poiciloptilus	Endangered	Records restricted to post 2007 to account for estimated 11-year lifespan of the species	The south-eastern Australian subpopulation of the species is considered as one population for this assessment. All records within the Strategic Assessment Area are therefore considered part of the same population	All populations were considered to be important as the species is endangered
Chalinolobus dwyeri	Vulnerable	All BioNet records for the Strategic Assessment Area were included in the assessment	The species is known to breed in very few locations across NSW and the distance bats move from the maternity roost to over wintering roosts has not been established, but is likely to be less than 100 km (DoEE, 2018). As such all records within the Cumberland subregion are considered likely to be from the same breeding population	The population of Large-eared Pied Bats was considered important within the Strategic Assessment Area because it met the following criteria: A population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important
Commersonia prostrata	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Populations were considered to constitute clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	All populations were considered to be important as the species is endangered
Cynanchum elegans	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Little is known of the reproduction and dispersal ecology of C. elegans (DoEE, 2018). As part of this assessment, a population was considered to be clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	All populations were considered to be important as the species is endangered
Dasyurus maculatus maculatus	Endangered	BioNet records from 1999 onwards were considered current for the assessment	All records within an area covered by the average male home range (up to 5,512 ha) were considered a single population	All populations were considered to be important as the species is endangered
Deyeuxia appressa	Endangered	All available BioNet records were used to identify populations, with no date restrictions	There are not thought to be any extant populations of this species, as there are no recent records of species, and it is considered possible that the species is now extinct	All populations were considered to be important as the species is endangered

Scientific Name	Cth status	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Eucalyptus benthamii	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	There is limited information available regarding pollination and dispersal thresholds for *E. benthamii.* Therefore, a population was considered to constitute clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	Populations of *E. benthamii* were considered important because they met one or more of the following criteria: • A population identified or inferred in a Commonwealth conservation advice, plan, final determination, or other relevant policy document as being important • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program • A large population • A population within a conservation reserve • A population that is important for maintaining the Extent of Occurrence of a species
Genoplesium baueri	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Records within 500 m of each other have been considered to be a single population	All populations of *G. baueri* have been considered as important as the species is endangered
Grevillea parviflora subsp. *parviflora*	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Little is known about the life cycle of *G. parviflora* subsp. *parviflora.* Flowers are insect pollinated, and it is likely that seeds have limited dispersal distances (probably <2 m) (DoEE, 2018) Populations were identified as clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	Populations of *G. parviflora* subsp. *parviflora* were considered important because they met one or more of the following criteria: • A population that is important for maintaining the Extent of Occurrence of a species • A population within a conservation reserve • A large population
Heleioporus australiacus	Vulnerable	BioNet records were used from 2008 onwards based on the approximate 10 year life-span of the species (noting that this only excluded two records from the assessment – both with limited accuracy from 1974 and 1913)	Records within 300 m were considered to be a population	The populations of Giant Burrowing Frog were considered important within the Strategic Assessment Area because they met the following criteria: A population within a conservation reserve

Scientific Name	Cth status	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Hibbertia puberula subsp. *glabrescens*	Critically Endangered	All available BioNet records were used to identify populations, with no date restrictions	This species is known to occur in one location, as a single population. The translocation site has been planted with a number of individuals propagated from the Bankstown location	All populations of *H. puberula* subsp. *glabrescens* have been considered as important as the species is critically endangered
Hoplocephalus bungaroides	Vulnerable	Records of this species within the Strategic Assessment Area and Cumberland subregion were assessed to determine the age and accuracy of the record, the characteristics of the landscape in which the record is located, and the likelihood of persistence of the species in that locality due to subsequent removal of, or disturbance to, habitat	There is only one record of this species within the Strategic Assessment Area, which has been identified as a single population	No important populations have been identified for this species (all non-important)
Lathamus discolor	Critically Endangered	All available BioNet records were considered in the assessment	The species is considered to be a single migratory population. All records within the Strategic Assessment Area are therefore considered part of the same population	All populations were considered to be important as the species is critically endangered
Leucopogon exolasius	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	No important populations were identified for *L. exolasius*. All populations are non-important
Litoria aurea	Vulnerable	All available BioNet records from 1995 onwards were included in the assessment, based on the guidance in the EPBC Act Policy Statement 3.19 (DEWHA, 2009)	Populations were considered separate if records were more than 10km apart OR where landscape features interrupted connectivity, based on the guidance in the EPBC Act Policy Statement 3.19 (DEWHA, 2009)	The populations of Green and Golden Bell Frog were considered important within the Strategic Assessment Area because they met the following criteria: A population identified or inferred in a Commonwealth conservation advice, plan, final determination, or other relevant policy document as being important
Macquaria australasica	Endangered	All BioNet records have been included in the assessment	Populations in distinct rivers and streams are considered separate populations	All populations were considered to be important as the species is endangered
Melaleuca deanei	Vulnerable	Records in each population were interrogated to ascertain the likelihood	A population is considered to be individuals within 500 m of each other, as species dispersal is	Populations of *M. deanei* were considered important because they met one or more of the following criteria:

Scientific Name	Cth status	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
		of persistence based on the removal of, or disturbance to, habitat	unlikely to occur beyond this distance (NSW DECCW, 2010)	• A large population • A population within a conservation reserve • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
Micromyrtus minutiflora	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Populations were defined by clustered records connected by relatively intact and continuous vegetation and not separated by a distance of >1 km (approx.). This is based on the distance travelled by insect pollinators and potential unrecorded individuals	All populations of *M. minutiflora* were considered important within the Strategic Assessment Area because the species is identified as an SAII entity through the BC Act process
Persicaria elatior	Vulnerable	All available BioNet records were used to identify populations	Biological populations were defined based on clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollination	Populations of *P. elatior* were considered important because they met one or more of the following criteria: A large population (number of individuals)
Persoonia bargoensis	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	All recorded plants were mapped as a single population as occurrence of the species within the Plan Area spans 20 km, and genetic flow (fruit dispersal by birds and pollination) could potentially move across the population within the life span of each plant (expected to be 20 years (OEH, 2019b))	Populations of *P. bargoensis* were considered important within the Strategic Assessment Area because they met one or more of the following criteria: • A large population (number of individuals) • Only known population of this species
Persoonia glaucescens	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Individuals within 500 m of each other are likely to be interbreeding and are therefore considered to be the same population	Populations of *P. glaucescens* were considered important because they met one or more of the following criteria: • A population that is important for maintaining the Extent off Occurrence of a species • A population within a conservation reserve • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program

Scientific Name	Cth status	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Persoonia hirsuta	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	All populations of *P. hirsuta* are considered to be important as the species is endangered
Persoonia nutans	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Populations were defined by clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	All populations of *P. nutans* are considered to be important as the population is endangered
Petauroides volans	Vulnerable	BioNet records were restricted to post 2003 to account for the average 15 year lifespan of the species	The species occupies a relatively small home range with an average size of 1 to 3 ha and they have a low dispersal ability. Records separated by several kilometres and/or cleared developed areas were identified as separate populations	The populations of Greater Glider were considered important within the Strategic Assessment Area because they met the following criteria: A population within a conservation reserve
Pimelea curviflora var. *curviflora*	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Populations were defined by clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	Populations of *P. curviflora* var. *curviflora* were considered important because they met the following criteria: A large population
Pimelea spicata	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators	All populations of *P. spicata* are considered to be important as the species is endangered
Pomaderris brunnea	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Records within 1 km of one another are considered a single population	Populations of *P. brunnea* were considered important because they met one or more of the following criteria: • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program • A population within a conservation reserve • A large population

Scientific Name	Cth status	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Pommerhelix duralensis	Endangered	All available BioNet records were used to identify populations, with no lifespan restrictions	Records have been grouped into populations based on geographic restrictions and connectivity between patches of suitable vegetation	All populations were considered to be important as the species is endangered
Pteropus poliocephalus	Vulnerable	Based on other bat species, the life expectancy is likely to be between two and ten years. BioNet records have been taken from 2008 onwards	The Grey-headed Flying-fox is considered to be a single population across its range (DoEE, 2017)	The population of Grey-headed Flying-foxes was considered important within the Strategic Assessment Area because it met the following criteria: • A population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important
Pterostylis saxicola	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Records within 500 m of one another considered a single population	All populations of this species were considered to be important as the species is endangered
Pultenaea parviflora	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat	Records within 500 m of each other were considered to be a single population	Populations of *P. parviflora* were considered important because they met one or more of the following criteria: • A population is important for maintaining the Extent of Occurrence of a species • A population within a conservation reserve • A large population • Is associated with a commitment made under the Sydney Growth Centres conservation program • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
Rostratula australis	Endangered	Records restricted to post 2002 to account for estimated 16-year lifespan of the species	All records within the Cumberland subregion are representative of a portion of the east coast population and therefore records in the Strategic Assessment Area have been grouped as one single population	All populations were considered to be important as the species is endangered

D. Additional detail on BAM plots recorded within the nominated areas

Additional detail on the BAM plots recorded in the nominated areas is provided in Table D-1. See Section 11.3.2 in Part 3 for context.

VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 4 Contents

Part 4 List of Figures

Part 4 List of Tables

This Part describes:

- Avoiding and minimising impacts under the Plan (Chapter 14)
- Managing indirect impacts of the urban and industrial, infrastructure, intensive plant agriculture, and transport development under the Plan (Chapter 15)
- Adaptive management for addressing uncertainty (Chapter 16)

14 Avoiding and minimising impacts

14.1 INTRODUCTION

The Department of Planning, Industry and Environment (the Department) and Transport for NSW have undertaken planning processes to locate and design the urban capable land in the nominated areas and the major transport corridors to avoid and minimise impacts on biodiversity values. This has been undertaken in accordance with:

- Guidance provided under section 8 of the Biodiversity Assessment Method (BAM)
- *Conservation measures in strategic applications for biodiversity certification: Guidance for planning authorities* (DPIE, 2020a)
- Commonwealth Terms of Reference (ToR)

This Chapter:

- Defines avoidance in the context of the Plan and explains how avoidance calculations were determined
- Sets out the regulatory requirements for avoiding and minimising impacts under the BAM and ToR
- Describes the steps taken and processes to avoid and minimise impacts for:
    - Urban and industrial development, intensive plant agriculture and infrastructure within urban capable land
    - Major transport corridors
    - Essential infrastructure
- Describes the avoidance and minimisation outcomes for:
    - Urban and industrial development, intensive plant agriculture and infrastructure within urban capable land
    - Major transport corridors
    - Essential infrastructure

This Chapter summarises avoidance and minimisation outcomes for biodiversity values generally. Further details on avoidance outcomes for specific matters, including serious and irreversible impacts, prescribed impacts, and each Commonwealth-listed species and threatened ecological community, are provided in:

- Chapter 24 (prescribed impacts)
- Chapter 25 (SAII)
- Chapters 29 to 31 (each Commonwealth-listed species and TEC)

The different types of development under the Plan were subject to different avoidance processes. It is important to note that for the major transport corridors and essential infrastructure, the avoidance process is not yet complete as detailed design will be undertaken in the future at the time the projects are proposed (see Part 2). The Plan includes commitments to ensure these future processes lead to acceptable avoidance outcomes for these developments.

Avoiding and minimising impacts to biodiversity values is an important part of the assessment process. It is a critical step in minimising the impacts of the development and reducing the need for commitments and actions to offset those impacts. It also provides opportunities to protect important areas of remaining biodiversity, through the application of commitments and actions (such as biodiversity stewardship agreements) to avoided lands.

Avoiding and minimising impacts on biodiversity values is fundamental to demonstrating that the commitments and actions proposed for a strategic biodiversity certification adequately address the impacts of the development under section 8.7 of the *Biodiversity Conservation Act 2016* (see Part 7).

Documenting the process is also a requirement of the Commonwealth ToR (section 4.5(2)).

14.2 DEFINITION OF AVOIDANCE

This section describes the definition of avoidance and the method used to calculate avoidance for urban and industrial development, intensive plant agriculture and infrastructure within urban capable land.

There may be several reasons why land is avoided and not impacted under the Plan, including because:

- Land has high biodiversity value and is avoided for biodiversity purposes
- Land is not suitable for development or biodiversity certification
- Land is excluded from the area proposed for development or biodiversity certification

Under the BAM, avoidance refers to land that is suitable for development and included in the area proposed for development or biodiversity certification but has been avoided and not certified because of its biodiversity value. Land not impacted because it is unsuitable for development, or land that has been excluded from the area proposed for development is not considered to have been avoided under the BAM.

In accordance with the BAM, the Assessment Report determines avoidance outcomes for biodiversity values on the basis of the amount of land avoided because of its biodiversity value. The amount of land 'avoided' for other purposes (i.e. the land is not suitable for development) is also presented in this report for additional context.

14.2.1 DEFINITION OF LAND AVOIDED FOR OTHER PURPOSES

For the Assessment Report, the following land is considered to be avoided for other purposes:

- Land that is mapped as a riparian corridor associated with a Strahler order 3 stream or above (or Strahler order 2 streams with mapped vegetation, adjacent to avoided lands or that contribute to landscape connectivity). Riparian buffers applied are consistent with the *Water Management Act 2000*:
    - Strahler stream order 2 - buffer 20 m either side
    - Strahler stream order 3 - buffer 30 m either side
    - Strahler stream order 4 and above - buffer 40 m either side
- State protected land within avoided lands (>18 degrees slope, considered too steep for urban development)

Flood-prone land is not included in the list of land avoided for other purposes because significant development does occur within flood-prone land in the Plan Area. The use of fill and other flood-mitigation works means that flood-prone land does not necessarily constrain urban development.

14.2.2 DEFINITION OF EXCLUDED LAND

Some land within the nominated areas was not considered for inclusion in the area proposed for development and has therefore been identified as 'excluded' land. These lands include:

- Existing protected land, including reserves and established offset sites
- Council owned land which is zoned for environmental conservation, environmental management, or recreation
- Commonwealth land, such as Defence Establishment Orchard Hills
- Lands within the nominated areas already assessed as part of another development approval (Bingara Gorge), or lands progressing through an alternate assessment (Mount Gilead, Menangle Park, Sydney Metro Stage 1)
- Lands already developed (existing urban areas, urban land zones and roads)

14.2.3 ALLOCATION OF LAND TO AVOIDANCE CATEGORIES

As land can be allocated to several categories (e.g. land can be allocated to both 'riparian corridor' and 'excluded land') a prioritisation process was used to allocate land to one of the four categories used.

The priority applied to the classification of land for avoidance calculations is provided in Table 14-1.

Table 14-1: Priority applied to classification of lands for avoidance calculations

Priority	Avoidance category	Input data
1	Biodiversity certified	Urban capable land (including urban and industrial development, infrastructure, and intensive plant agriculture) and major transport corridors
2	Excluded/Non-certified – Western Sydney Aerotropolis	Land in the nominated areas already assessed as part of another development approval or lands progressing through an alternate development assessment (Bingara Gorge, Mount Gilead, Menangle Park, Sydney Metro Stage 1) Land already developed (existing urban areas, urban land zones and roads) Land not available to development (existing protected land, council owned land which is zoned for environmental conservation, environmental management or recreation, Commonwealth land and easements) Land identified as 'Environment and Recreation' lands within the updated Western Sydney Aerotropolis Stage 1 Structure Plan
3	Avoided for other purposes	Land that cannot be feasibly developed due to topography (area of steep slope within avoided lands) or is land that is mapped as a riparian corridor associated with a Strahler order 3 stream or above (or Strahler order 2 streams with mapped vegetation, adjacent to avoided lands or that contribute to landscape connectivity)
4	Avoided for biodiversity purposes	All other land (apart from land to be developed under the Plan)

14.2.4 METHOD TO CALCULATE AVOIDANCE OUTCOMES

The method to calculate avoidance outcomes within the nominated areas is as follows:

Step 1: Determine the existing area (in hectares) of each biodiversity value within the nominated areas

Step 2: Determine the area impacted by urban capable land and major transport corridors for each biodiversity value

Step 3: Determine the area of each biodiversity value within excluded land

Step 4: Determine the area of each biodiversity value avoided for other purposes

Step 5: Determine the area of each biodiversity value avoided for biodiversity purposes (this is done by subtracting the summed amount (hectares) in steps 2, 3, and 4 from step 1)

14.3 REGULATORY REQUIREMENTS

The BAM and ToR both require the Assessment Report to demonstrate how impacts to biodiversity values have been avoided and minimised. The BAM provides more detailed guidance than the ToR on how avoidance should be achieved.

14.3.1 BC ACT REQUIREMENTS

BAM

Section 8 of the BAM requires the BCAR to describe the actions taken to avoid and minimise impacts on biodiversity values through the location and design of the urban capable land and transport corridors on:

- Native vegetation and habitat
- Prescribed impacts

The BCAR must describe how actions taken to avoid and minimise impacts on biodiversity values have influenced both the project location and the design of the project. The BCAR should explain how impacts have influenced the location and design of the urban capable land and transport corridors, including the extent to which areas of higher biodiversity value have been identified and then excluded from the urban capable land and transport corridors.

The BAM provides that direct impacts on native vegetation and habitat can be avoided and minimised by:

- **Development location considerations:**
  - Locating development in areas where there are no or minimal biodiversity values
  - Locating development in areas where native vegetation or habitat is in the poorest condition (as measured by the Vegetation Integrity score for each vegetation zone)
  - Avoiding habitat for species with higher biodiversity risk weightings
  - Avoiding critically endangered or endangered TECs
  - Avoiding areas that maintain habitat connectivity between areas of nearby habitat
- **Development design considerations:**
  - Reducing the urban capable land and transport corridors of the project
  - Providing structures to enable species to move across barriers or habitat gaps
  - Making provision for the ecological restoration and ongoing maintenance of retained native vegetation

The BAM provides that prescribed impacts can be avoided and minimised by:

- **Development location considerations:**
  - Locating urban capable land or sub-surface works to avoid habitat features associated with prescribed impacts (such as caves, cliffs, water bodies, important non-native vegetation, or areas of habitat connectivity)
  - Avoiding areas that maintain habitat connectivity between areas of nearby habitat
- **Development design considerations:**
  - Designing project elements to minimise interactions with biodiversity values, such as designing fencing to prevent animal entry to roads or transport corridors or roads
  - Designing the project to maintain hydrological processes
  - Design the project to avoid and minimise downstream impacts on water bodies by controlling water quality

Section 8.1.1.4 and section 8.2.2.2 of the BAM requires the BCAR to:

- Analyse alternative locations for urban capable land that would further avoid or minimise impacts
- Justify the location of the final urban capable land

In justifying the selection of final urban capable land, a rationale should be provided for the location of the boundaries where they do not avoid areas of biodiversity value, such as strategic planning reasons.

GUIDELINES UNDER THE BAM

In addition to the BAM, the *Conservation measures in strategic applications for biodiversity certification: Guidance for planning authorities* (DPIE, 2020a) provides a set of guiding principles for demonstrating that commitments and actions proposed for a strategic biodiversity certification adequately address impacts on biodiversity values.

The first principle relates to avoidance and requires that:

> *"Principle 1 – Potential serious and irreversible impacts are avoided and minimised"*

14.3.2 EPBC ACT REQUIREMENTS

Section 4.5(2) of the ToR requires the SAR to include an analysis of the likely adverse impacts of actions of the Plan on protected matters, including consideration of:

> *"How impacts on protected matters will be avoided through land use planning and other measures…"*

14.4 STEPS TAKEN AND PROCESSES TO AVOID AND MINIMISE IMPACTS

The steps taken and future processes to avoid and minimise impacts for the different types of development under the Plan are summarised in Table 14-2 and described in more detail in section 14.4.1 to section 14.4.3.

The avoidance process involved:

- Strategic planning to determine the broad locations of the nominated areas and major transport corridors
- Detailed design to determine the urban capable land footprint and transport infrastructure footprint within the nominated areas and major transport corridors

For the major transport corridors and essential infrastructure, the avoidance process is not yet complete as detailed design will be undertaken in the future at the time the project is proposed (see Part 2). The Plan includes commitments to ensure this future process leads to acceptable avoidance outcomes for these developments.

Table 14-2: Steps taken and future processes to avoid and minimise impacts for the different types of development

Development under the Plan	Avoidance process	Implementation of avoidance process
Urban and industrial development, intensive plant agriculture and infrastructure within urban capable land	Step 1: Strategic planning to determine the locations of the nominated areas	Completed prior to development of Plan
	Step 2: Detailed design of urban capable land footprint within the nominated areas	Completed as part of development of Plan Statistics on biodiversity values avoided within nominated areas are provided in Section 14.5.1
Major transport corridors	Step 1: Strategic planning to determine the locations of the major transport corridors	Completed prior to development of Plan
	Step 2: Future detailed design to determine the location of the infrastructure within the transport corridor footprints	To be completed in the future at the time the project is proposed in accordance with commitments under the Plan
'Essential infrastructure' within avoided land	Future strategic planning and detailed design to determine the location of infrastructure within avoided land	To be completed in the future at the time the project is proposed in accordance with commitments under the Plan

14.4.1 URBAN AND INDUSTRIAL DEVELOPMENT, INTENSIVE PLANT AGRICULTURE AND INFRASTRUCTURE

Consistent with Section 8.1.1.2 of the BAM, the process to identify the location of urban and industrial development, intensive plant agriculture and infrastructure within urban capable land in the nominated areas was an iterative one that began early in the assessment process before the final data on biodiversity values was completed.

The urban capable land was identified in three phases:

- Strategic planning to locate the nominated areas
- Initial development of footprints through Land Use and Infrastructure Implementation Plans (LUIIP)
- Iterative refinement of the footprints through development of the Plan and assessment of impacts

STRATEGIC PLANNING TO DETERMINE THE LOCATION OF THE NOMINATED AREAS

The location of the nominated areas was determined through various strategic planning strategies and investigations over many years. Two key planning strategies that informed the location of the nominated areas were:

- *A Plan for Growing Sydney* (DPE, 2014) – this identified the general location of Wilton Growth Area (Wilton) and Greater Macarthur Growth Area (GMAC) and the Badgerys Creek Airport precinct, which was subsequently refined further by the Department to become WSA
- *A Metropolis of Three Cities* (GFC, 2017) – this identified the general location of Greater Penrith to Eastern Creek Investigation Area (GPEC) and establishes a 40-year vision for Sydney as a global metropolis of three cities, including the Western Parkland City covering the nominated areas

The nominated areas were located based on a broad range of strategic planning considerations, including:

- Proximity to current and planned locations of employment

- The cost of infrastructure provision including roads, water, sewerage, public transport, schools, and health facilities
- The economic and social cost to communities of having poor access to employment and services, including transport
- Environmental constraints, including biodiversity values

Action 2.4.2 of *A Plan for Growing Sydney* (DPE, 2014) aimed to develop a long-term framework for the identification of new nominated areas to improve the management of future land release in Sydney. In preparing a framework for the identification of nominated areas, Action 2.4.2 indicates that a range of issues should be considered, including:

- The value of land for drinking water supply, agriculture, environmental management and other purposes
- Constraints to development, including environmental constraints and natural hazards

The Department undertook investigations into the location of the nominated areas in accordance with Action 2.4.2.

LAND USE AND INFRASTRUCTURE IMPLEMENTATION PLANS

Land Use and Infrastructure Implementation Plans (LUIIP) are currently being prepared for the nominated areas. LUIIPs are high level plans for the growth and development of each nominated area. They identify the location of urban capable land, broad land uses and the location of infrastructure, as well as housing and employment targets.

Indicative urban capable land had been developed as part of the early preparation of the LUIIPs, including for Wilton, GMAC, and part of WSA. Urban capable land was identified largely on the basis of avoiding large patches of intact native vegetation (Eco Logical Australia, 2017), including:

- BIO Map core areas and corridors (OEH, 2015)
- Priority Conservation Lands identified as part of the Cumberland Plain Recovery Plan methodology report (DECCW, 2010)

The early LUIIP footprints provided the starting point for the iterative refinement of the footprints through development of the Plan. Any changes made through this process are, or will ultimately be, reflected in the LUIIPs.

ITERATIVE REFINEMENT OF URBAN CAPABLE LAND THROUGH DEVELOPMENT OF THE PLAN

Development of the Plan provided an important opportunity to iteratively refine the initial urban capable land with the aim of avoiding and minimising impacts to biodiversity values. The process involved:

- Compilation of data on biodiversity values of each nominated area
- Development of criteria to identify priorities for avoidance of biodiversity values
- Workshops to apply the avoidance criteria to each nominated area and refine urban capable land
- Consultation with key stakeholders and resolution of issues
- Finalisation of initial urban capable land

Compilation of data on biodiversity values

The best available data on the biodiversity values of each of nominated area was compiled and used to identify areas of high biodiversity value and inform the location and design of the urban capable land.

The data on biodiversity values was compiled into a series of GIS datasets and used in two phases:

- Initial urban capable land was identified based on preliminary data on biodiversity values
- Finalisation of initial urban capable land was undertaken based on final data on biodiversity values

The preliminary data used to inform the initial urban capable land comprised:

- Draft native vegetation maps of each nominated area showing:
  - Extent and condition of Plant Community Types (PCTs)
  - Extent and condition of NSW-listed TECs
- Threatened species records derived from BioNet for all species needing to be assessed in the Assessment Report (all Commonwealth-listed Category 1 matters and all NSW-listed candidate species – see Part 3)

- Draft habitat maps for threatened species where available, particularly including Koala habitat mapping

The data used to finalise the initial urban capable land comprised:

- Final native vegetation maps of each nominated area showing:
  - Extent and condition of PCTs
  - Extent and condition of Commonwealth-listed and NSW-listed TECs
- Threatened species records derived from BioNet for all species needing to be assessed in the Assessment Report (all Commonwealth-listed Category 1 matters and all NSW-listed candidate species)
- Final habitat maps for threatened species where available

A more detailed description of each dataset used to inform the urban capable land is provided in Part 3.

Development of avoidance criteria

Criteria were developed to identify priorities for the avoidance of biodiversity values. The purpose of the criteria was to provide detailed guidance, consistent with the guidance provided in the BAM, to inform decisions about the location and design of the urban capable land through the series of workshops with precinct planners and ecologists.

The avoidance criteria identified priorities for avoidance within three main categories:

- TECs and PCTs, including condition
- Threatened species
- Ecological processes

In applying the criteria, the highest priority within each category was given equal weight (the TEC/PCT priority 1 was given equal weight to the threatened species priority 1).

The avoidance criteria are provided in Box 1.

BOX 1: AVOIDANCE CRITERIA AND CATEGORIES

(a) TECs and PCTs

1. Critically endangered ecological communities (CEECs) or PCTs ≥90% cleared in large patches and in good condition; or serious and irreversible impact (SAII) entities (TECs)
2. Endangered ecological communities (EECs) or PCTs ≥70% to <90% cleared in large patches and in good condition
3. PCTs ≥50% to <70% cleared in large patches and in good condition
4. PCTs <50% cleared in large patches and in good condition

(b) Threatened species

1. Known habitat^ for critically endangered species, SAII entities (species), Saving Our Species (SOS) species polygons (where species-specific habitat is present), or large populations of threatened species (relative to typical size for that species); or known primary koala habitat
2. Known habitat^ for endangered species or known secondary koala habitat
3. Known habitat^ for vulnerable species

(c) Ecological processes

1. Land identified as priority conservation lands, BIO Map core areas, or important local habitat corridors for key species including Koalas
2. Land identified as BIO Map regional corridors or as areas that provide significant opportunities to support important local habitat corridors for key species, including Koalas
3. Areas identified on the Biodiversity Values Map

Boundary rationalisation

Consider removing:

- Small nodes or isolated patches of features identified in (a), (b) or (c) if future land use change will lead to significant edge effects and low viability over the timeframe identified, and there is no feasible opportunity to enhance connectivity and extent
- Corridors that do not link important areas of habitat, including 'blind corridors'

^ As indicated by BioNet records or recent survey data

Application of avoidance criteria

The avoidance criteria were applied through a series of workshops to each nominated area to identify areas of high biodiversity value and priorities for avoidance. The workshops included the following participants:

- The Department's team that is preparing the Plan
- Accredited assessors and other expert ecologists who advised on biodiversity values and priorities
- The Department's precinct planning team who advised on urban development priorities and targets

Urban capable land identified in the LUIIP processes for Wilton, GMAC and part of WSA was used as a starting point. The workshops involved:

- Reviewing the data on biodiversity values compiled into a series of GIS datasets. Accredited assessors and other expert ecologists reviewed the accuracy of the data and made adjustments where necessary. As part of this process, consultation was undertaken with field ecologists to verify the accuracy of data
- Identifying areas of high biodiversity value and priorities for avoidance based on the identified criteria. This work focused on identifying priority 1 and priority 2 avoidance areas within each nominated area
- Rationalising the urban capable land to remove areas of biodiversity value that comprised:
    - Small nodes or isolated patches where future land use change will lead to significant edge effects and low viability and in which the opportunity to enhance connectivity and extent are not feasible
    - Habitat corridors that do not link important areas of habitat, including 'blind corridors'
- Identifying where priorities for avoidance of biodiversity were inconsistent with:
    - Indicative urban capable land identified in current LUIIPs, and/or
    - The achievement of urban development priorities reflected in relevant planning strategies and plans, including LUIIPs. These priorities included matters such as:
        - Urban planning/urban structure and design principles
        - Housing provision and dwelling targets
        - Transport and infrastructure provision and accessibility targets
        - Employment areas and targets
        - Open space provision and targets

Where priorities for avoidance of biodiversity values were inconsistent with urban development priorities, further consideration of the specific urban development imperative and needs, and further desktop investigation and validation of the biodiversity values of the site, was undertaken. Potential alternatives were explored, and negotiations undertaken between the Department's strategic assessment team and the Department's planning team to:

- Explain and justify urban development and biodiversity avoidance priorities
- Explore alternative development locations to achieve the urban development priorities
- Seek a balance between urban development and biodiversity priorities

Box 2 provides a case study of the application of the avoidance criteria.

BOX 2: CASE STUDY - MINIMISING IMPACTS TO BIODIVERSITY VALUES IN AN AREA TARGETED FOR URBAN GROWTH IN WILTON

Step 1: Map the biodiversity values in Wilton and integrate this information with development plans for the area

The development of lands in north Wilton precinct identified an opportunity for a recreation reserve in the northern end of the precinct to support open space targets. The land is largely pasture within a matrix of Shale Sandstone Transition Forest, which cover the full range of condition classes (intact, thinned, scattered trees and derived native grassland). The forested portions of this community comprise the CEEC under both the BC Act and EPBC Act. Furthermore, as part of the work to develop the Plan, the area for the proposed recreation reserve was identified as a priority for ecological restoration, including because the land contained a Koala corridor and the TEC

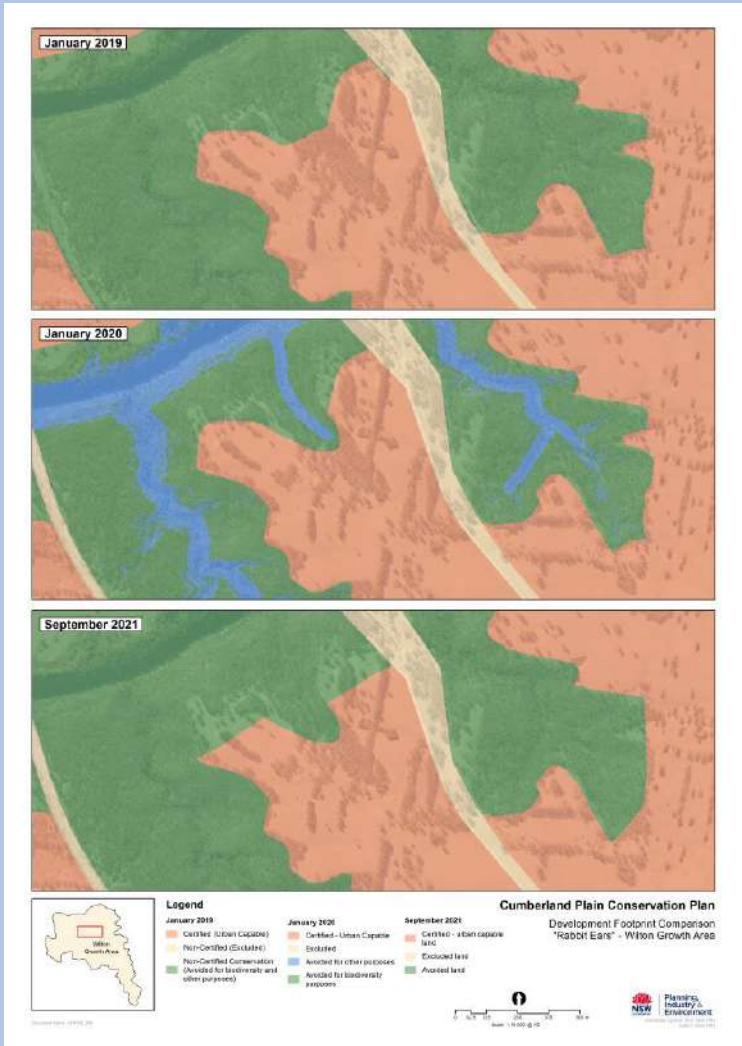
Step 2: Initial amendment of footprint to minimise impacts to biodiversity values

Discussions were undertaken between the Department and the landholder to explore opportunities to reduce impacts on biodiversity values while providing for the recreational reserve to support open space targets. This led to reducing the footprint of the reserve in key areas of biodiversity value, while still allowing for an access road for public access

Step 3: Further amend footprint and recreational design and use to further reduce impacts

The Department and the landholder met further to discuss opportunities to further amend the footprint and the recreational design and use of land to balance open space targets and impacts to biodiversity values. The agreed final design of the recreational reserve will focus on passive, constructed play, and will retain of some of the original recreational land uses as well as potentially including car parking facilities. This allowed for a more effective wildlife corridor around the top of the Nepean River gorge to provide connectivity for animals such as Koala

These steps are reflected in the diagram below:



Public and key stakeholder consultation

Consultation was undertaken with key stakeholders on the indicative urban capable land boundary prior to public exhibition of the Plan and Assessment Report. This occurred through:

- Public exhibition of draft LUIIPs that identified indicative urban capable land
- Targeted consultation with planning authorities, including Councils, to clarify urban development priorities particularly where these were inconsistent with avoidance priorities
- Consultation with accredited assessors and other expert ecologists to verify the accuracy of the data, particularly where urban development priorities were inconsistent with avoidance priorities
- Consultation with developers and landholders within the nominated areas to gain access to additional data

Public exhibition of the Plan and Assessment Report provided further opportunity for stakeholders to comment on the avoidance outcomes and urban capable land boundary. This led to the adjustment of the urban capable land boundary in some cases. Key adjustments were made in relation to:

- Advice from the Office of the NSW Chief Scientist & Engineer – the office provided two sets of advice to the Department on the adequacy of the protection of Koala relating to the Plan. The advice included a range of principles and recommendations, including that Koala movement corridors should meet a minimum average width of 390 metres. This led to changes to the urban capable land boundary in Wilton and GMAC
- Existing easements – all existing easements are to be certified except where:
    - Easements intersect or are adjacent to avoided land – these remain excluded
    - Easements intersect or are adjacent to excluded land – these remain excluded
    - Roads remain excluded (except major Transport for NSW roads identified in the Plan)
    - Sydney Water Canal – this remains excluded
- 'Environment and Recreation' land in Western Sydney Aerotropolis (WSA) – this land was identified in the public exhibition version of the Plan as 'Non-certified – Western Sydney Aerotropolis' and is to be certified under the Plan and included in the urban capable land. Note that this land was previously not considered avoided land and was included in the broad definition of excluded land in the public exhibition version of the Plan and for the purposes of the avoidance statistics in the public exhibition version of the Assessment Report
- Riparian buffers – Strahler order 1 and 2 waterways are to be certified (and Strahler order 3, 4 and above waterways are to remain 'avoided for other purposes'). Exceptions include where the section of Strahler order 2 waterways contain mapped vegetation, are adjacent to avoided land or contribute to landscape connectivity (these will be considered 'avoided for other purposes' – see section 14.2) and where the section of Strahler order 3 waterways are isolated in the landscape and do not support a landscape scale corridor (these will be certified and not avoided)
- Submissions from landholders – where landholders made submissions that included on-site data collected by qualified ecological consultants that indicated native vegetation mapping was inaccurate on their property. Where it was determined the mapping needed updating, this led to re-consideration of previous avoidance decisions and in some cases, changes to the urban capable land boundary consistent with the avoidance criteria (see Box 1)
- Development applications – where development applications were approved within avoided land, updates were made to the urban capable land boundary to reflect these previous decisions

COMMITMENTS FOR AVOIDANCE AND MINIMISATION

The Plan includes a commitment (Commitment 2) to avoid and minimise impacts to 4,505 hectares of high biodiversity value area through strategic planning of the nominated areas. This area comprises the avoided land.

The Plan also includes a commitment (Commitment 5) to mitigate indirect impacts from urban and other development that would lead to avoidance of impacts on key habitat features within urban capable land. These include:

- Retain large trees (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction
- Retain areas of high density Proteaceae shrubs where possible, particularly along riparian corridors

Several actions under Commitment 2 will provide protection to avoided land and ensure the impacts of any future urban development proposed on avoided land is minimised. These include:

- Introduction of an environmental planning instrument to apply development controls to protect important biodiversity on avoided land under the Plan. This comprises the SEPP (Strategic Conservation Planning). The development controls included in the SEPP are described in more detail in Part 2
- Preparation of a Ministerial Direction under section 9.1 of the EP&A Act to restrict rezoning of avoided land from its current zone to a zone that permits a more intensive land use. This is described in more detail in Part 2
- Locate asset protection zones wholly within urban capable land. The SEPP (Strategic Conservation Planning) gives this requirement legal effect. This is described in more detail in Part 2
- Monitor the impacts of any proposed development on avoided land through the Plan's reconciliation accounting process. The reconciliation process is described in more detail in Part 7

14.4.2 MAJOR TRANSPORT CORRIDORS

Avoidance and minimisation of impacts from the major transport corridors is being undertaken in two stages:

- Strategic planning to determine the locations of the major transport corridors. This was completed under Transport for NSW planning processes prior to development of Plan
- Future detailed design to determine the location of the infrastructure within the transport corridor footprint. This is to be completed in the future at the time the project is proposed in accordance with commitments under the Plan

STRATEGIC PLANNING TO DETERMINE THE LOCATIONS OF THE MAJOR TRANSPORT CORRIDORS

The process for identifying, selecting, and designing future corridors and transport projects involves a detailed set of steps and processes to ensure optimum infrastructure, environmental, social and economic outcomes are achieved. The *Planning guideline for Major Infrastructure Corridors* (DPE, 2016) sets out the recommended processes for infrastructure agencies to follow through the different phases of corridor planning.

The guideline provides advice in relation to the three broad phases:

- Strategic planning – identification
- Corridor planning and selection
- Infrastructure delivery

The first two phases lead to the identification and protection of major transport corridors. As part of this process, a Strategic Environmental Assessment (SEA) is prepared which provides an assessment of the environmental, economic, and social impacts of reserving the corridor. SEAs are non-statutory documents that assist in the planning and decision-making process for the community and Government. They are subject to public consultation and include justification for a preferred corridor alignment and provide information on the assessment of alternative corridor alignments.

In making decisions on corridor selection, infrastructure agencies undertake a constraints analysis and multi-criteria comparison of options. These include consideration of a wide range of factors including:

- Aboriginal heritage
- Biodiversity
- Costs
- Engineering and construction limitations
- Land use and property impacts
- Landscape character and visual amenity
- Noise and vibration
- Non-Aboriginal heritage
- Socio-economic considerations
- Soils, geology, and contamination
- Transport planning
- Water quality and hydrology

Example of SEA process – location of the OSO corridor

The Draft SEA for the OSO (AECOM, 2018) sets out the process used to identify the preferred location of the OSO corridor in the Plan (see Part 2). Transport for NSW commissioned the OSO study "to identify the most appropriate location for the corridor and to protect land within that corridor for the future provision of critical road and freight rail infrastructure". To do so, the SEA included evaluating legislative and policy frameworks, identifying regional and local baseline conditions, consulting with the community and stakeholders, a strategic assessment of options for the corridor, and an evaluation of the social, economic, and environmental consequences of the OSO.

The process for corridor identification was conducted in alignment with the *Planning Guidelines for Major Infrastructure Corridors* (DPE, 2016). The method for identifying the recommended corridor involved seven steps (AECOM, 2018):

Identifying a study area

The investigations for the OSO began with a broad OSO study area that was used to identify high level environmental attributes, along with the constraints, capacity, and opportunities within the area. The study area was refined during the OSO study based on stakeholder and community feedback, and to better suit the project objectives.

Understanding constraints and opportunities

A comprehensive review of the environmental, social, and engineering constraints and opportunities within the refined study area was conducted to identify a corridor that balances benefits and impacts. The environmental factors involved in this process include but are not limited to ecology and biodiversity, bushfire hazard, Aboriginal and non-Aboriginal heritage, soils and contaminated land, and water resources.

Developing guiding principles

A list of guiding principles was developed to identify a long list of corridor options. The principles were rated as either required, highly desirable, or desirable. The guiding principles were grouped into three sections: environment and land use, strategic planning, and engineering. The following principles relate to biodiversity:

- *Avoiding reserves including national parks and nature reserves (excluding regional parks)* (required)
- *Avoiding gazetted reserves (regional parks)* (highly desirable)
- *Avoiding lands identified as Priority Conservation Lands* (highly desirable)

Identifying corridor options

A variety of tools such as specialist advice and computer software were used to identify a long list of corridor options in alignment with the guiding principles and fatal flaw analysis (refer to the draft SEA for further information) (AECOM, 2018). The following 'fatal flaw' issue relevant to biodiversity values was considered:

- *Impacts on gazetted reserves including national parks and nature reserves (excluding regional parks)*

Evaluating corridor options

Various assessment and screening methods were applied to the long list of corridor options. A multi-criteria analysis (MCA) was used to evaluate corridor options and refine the long list to a short list.

Selecting a recommended OSO corridor

The MCA was used to select a recommended corridor option from the short list. Once this option was identified, it was further investigated and reviewed. Table 14-3 identifies the constraints and opportunities of recommended corridors.

Consultation on the recommended corridor

The public consultation period is intended to allow stakeholders and the community to provide feedback on the final corridor, after which a final SEA will be prepared.

The recommended corridor

The recommended corridor shown in the Plan (see Part 2) was chosen as it balances social, environmental, engineering, and current land use. The chosen corridor is considered to avoid where possible ecologically sensitive areas, residential

areas, major infrastructure, community facilities, open spaces, and existing schools. The process involved consultation and engagement with key agencies, land holders and community groups, along with the Department of Planning and Environment, and EES (AECOM, 2018).

Once the recommended corridor was identified, a desktop review of biodiversity was conducted to identify areas of vegetation considered significant habitat for threatened flora and fauna and a strategic assessment of the corridor was conducted that considered potential social, environmental, and economic impacts (AECOM, 2018).

Table 14-3: Avoidance or non-avoidance of reserves, national parks, and priority conservation lands within each section of the recommended corridor and relevant justification for non-avoidance (summary from AECOM, 2018)

Section of the OSO corridor	Avoidance or impacts to reserves, national parks, and priority conservation lands	Justification of impacts
1 (Box Hill to Dunheved)	The recommended corridor avoids: • Scheyville National Park, and ensures future expansion to Central Coast also excludes the park • South Creek riparian corridor through the centre of Wianamatta Regional Park The recommended corridor impacts: • Shanes Park • Wianamatta Regional Park	• Shanes Park – the placement is not expected to compromise planned urban development of the North West Growth Area • Wianamatta Regional Park – the alignment of the recommended corridor through Wianamatta Regional Park was considered reasonable to avoid impacts to planned and existing development, and in the context of potential impacts to more ecologically sensitive areas of the park
2 (Dunheved to Orchard Hills)	The recommended corridor impacts: • South Creek riparian corridor	• South Creek riparian corridor – placement along South Creek riparian corridor is preferred to reduce property impacts for hundreds of households near St Marys
3 (Orchard hills to Cobbitty)	No significant impacts to or avoidance of reserves, national parks, or priority conservation lands	• Avoids reserves, national parks, and priority conservation lands
4 (Cobbitty to Camden Park)	The recommended corridor avoids: • Where possible, the floodplain of Nepean River • Mater Dei biodiversity offset site • Allows perpendicular crossing of the Nepean River to minimise riparian impacts The recommended corridor impacts: • Priority conservation land in the locality	• Priority conservation land – the recommended corridor affects the least amount of priority conservation land when compared to other options east or west of the corridor
5 (Camden Park to Menangle	The recommended corridor avoids: • Razorback range There are no significant impacts to reserves, national parks, or priority conservation lands	Avoids reserves, national parks, and priority conservation lands

DETAILED DESIGN OF INFRASTRUCTURE WITHIN TRANSPORT CORRIDOR FOOTPRINTS

Because infrastructure alignments within the transport corridors are not final (see Part 2), the major transport corridors will be subject to a future process of avoidance and minimisation as part of the detailed design phase of each project to determine the location of the infrastructure within the transport corridor footprints. Note that for the purposes of the Assessment Report, the entire footprint of each major transport corridor is assumed to be impacted.

These future detailed design processes are different for the certified-major transport corridors within the nominated areas and the major transport corridors (strategically assessed only) outside the nominated areas, because of the different approvals that are being sought under the Plan for these corridors.

For the certified-major transport corridors, avoidance under the BAM has already been undertaken to locate the corridors, and no further avoidance is required to meet the requirements of the BC Act. However, Transport for NSW will undertake further avoidance and minimisation as part of business as usual through detailed design and in accordance with Commitment 3, including in consideration of the Plan's avoidance criteria (see Box 1).

For the major transport corridors (strategically assessed only), avoidance under the BAM has not been undertaken. Transport for NSW will be required to apply the avoidance requirements of the BAM (or equivalent) to meet each project's State Significant Infrastructure approval (or equivalent), in addition to applying other requirements for Commonwealth-listed matters in accordance with Commitment 4.

Both commitment 3 and 4 will lead to additional avoidance and minimisation outcomes for biodiversity values.

Certified - major transport corridors within the nominated areas

For the certified - major transport corridors within the nominated areas, the Plan commits to avoiding and minimising impacts to TECs, species and habitat through detailed planning and design (Commitment 3).

Actions under this commitment specify how Transport for NSW is to implement the commitment. This includes:

- Applying the Plan's avoidance criteria (see Box 1) during the planning phase of each transport project to guide and prioritise avoidance and minimisation of impacts to TECs, species, and habitat
- Including the biodiversity benefits of avoiding TECs, species, and habitat as well as the costs of offsets into the evaluation of route options (for example multi-criteria analysis)
- Locating asset protection zones, if required, within the major transport corridor footprint
- Minimising as far as possible using design refinements impacts on areas of high environmental value, where actions cannot feasibly or practically avoid impacts
- Providing to the Department a Clearing Reconciliation Report within 30 days of the completion of clearing for each major transport corridor project. The report will provide information on vegetation cleared, direct impacts to habitat and TECs, and a demonstration of how the Plan's Avoidance Criteria were applied. The report will be used to:
    - Inform the Plan's reconciliation accounting process to track impacts
    - Determine Transport for NSWs actual offsets liability. Actual offsets liability will be reconciled against Transport for NSW's scheduled forward payments for amounts outstanding or overpaid

The Department will publish impacts to biodiversity (including to MNES) within the major transport corridors through the Plan's annual updates and five yearly reviews (see Part 2).

There is also an action under the commitment in relation to third party activities within the major transport corridors undertaken by a party other than Transport for NSW. For these activities, Transport for NSW will ensure that third party proponents not included in the major transport corridors class of action are aware that they must consider the need for referral under the EPBC Act for actions likely to have a significant impact on MNES.

Major transport corridors (strategically assessed only) outside the nominated areas

For the major transport corridors (strategically assessed only) outside the nominated areas, the Plan commits to avoiding and minimising impacts to TECs, species and habitat, including the Outer Sydney Orbital (OSO) and Metro Rail Future Extension (MRFE) tunnel sections, in accordance with the:

- Major transport corridors class of action description, including the NSW State Significant Infrastructure (or equivalent) approvals process
- Biodiversity Assessment Method under the BC Act (or equivalent) (Commitment 4)

Commitment 4 includes avoiding and minimising impacts to known populations within the OSO and M7/Ropes Crossing Link Road corridors (Commitment 4.1), including:

- *Dillwynia tenuifolia*

- *Grevillea juniperina* subsp. *juniperina*
- *Pultenaea parviflora*
- *Cynanchum elegans*

Commitment 4 also includes avoiding and minimising impacts where possible within and adjacent to the OSO and MRFE tunnel sections, including (Commitment 4.2):

- Known populations and habitat of:
  - *Eucalyptus benthamii*
  - *Pomaderris brunnea*
  - *Pimelea spicata*
  - Cumberland Plain Land Snail
- Known populations and habitat and TECs within:
  - Mater Dei BioBank site within the OSO tunnel footprint near Camden
  - Registered Property Agreement site within the OSO tunnel footprint at Camden Airport
  - Metro Offset site within the OSO and MRFE tunnel footprints near Harrington Park
  - Nepean River and associated riparian corridor within the OSO tunnel footprint
  - Camden Golf Club at Narellan adjacent to the MRFE tunnel footprint
  - Mount Annan Botanic Gardens within the MRFE tunnel footprint

Commitment 4 also includes avoiding and minimising impacts where possible to environmental values within Commonwealth land sites, including known populations and habitat and TECs, as well as existing infrastructure and services, at (Commitment 4.3):

- Camden Airport
- Western Sydney University (Campbelltown Campus)
- 12 Werombi Road, Grassmere

Actions under Commitment 4 specify how Transport for NSW is to implement the commitment. This includes:

- Undertaking surveys to confirm biodiversity values and MNES, during planning phase of each transport project
- Including the biodiversity benefits of avoiding TECs, species and habitat as well as the costs of offsets into the evaluation of route options (for example multi-criteria analysis)
- Avoiding and minimising impacts to biodiversity values, including MNES, in accordance with the Biodiversity Assessment Method (or equivalent) and with specific consideration to the protected matters identified in Commitments 4.1, 4.2 and 4.3 during the environmental impact assessment phase of each transport project
- Offsetting impacts to biodiversity values, including MNES, in accordance with the BAM (or equivalent) and EPBC Act Environmental Offsets Policy, 2012, for any EPBC Act matters not covered by the BAM
- Reporting to the Department and executive implementation committee on vegetation cleared and adjustments to transport corridor boundaries identified through the NSW SSI approval (or equivalent) for each transport project. This will include reporting on:
  - Avoidance achieved within the major transport corridors
  - Any additional impacts outside the corridors for Commonwealth-listed species, populations or TECs
  - Any offsets to be secured under the NSW SSI approval and EPBC Act Environmental Offsets Policy, 2012

  The Department will use this information to track impacts and adjust Transport for NSW's offset liabilities through the Plan's reconciliation accounting process.

As for Commitment 3, the Department will publish impacts to biodiversity (including to MNES) within the major transport corridors through the Plan's annual updates and five yearly reviews (see Part 2).

14.4.3 ESSENTIAL INFRASTRUCTURE

Planning for essential infrastructure to support the nominated areas, such as water and electricity utilities, is in various stages of development, and the location of this infrastructure is not yet known.

The Plan is seeking approval under the EPBC Act for essential infrastructure to occur within the nominated areas outside urban capable land but not excluded land (i.e. within avoided land) (see Part 2).

It is important to note that approval is not being sought under the Plan for essential infrastructure within avoided land under the BC Act. Separate approval under the BC Act will need to be sought for essential infrastructure in the future (if the BC Act is triggered), along with planning and approvals required under the EP&A Act.

Essential infrastructure will be subject to a future process of avoidance and minimisation as part of the strategic planning and detailed design phase of each project. Each project will be managed through the NSW planning and approvals framework under the EP&A Act as current at the time of the project.

Essential infrastructure in avoided land must be carried out in accordance with:

- Guidelines for essential infrastructure development in Appendix A of the Plan
- Relevant commitments in the Plan

A description of the avoidance requirements and process for essential infrastructure is provided in Chapter 37.

14.5 AVOIDANCE AND MINIMISATION OUTCOMES

14.5.1 URBAN AND INDUSTRIAL DEVELOPMENT, INTENSIVE PLANT AGRICULTURE AND INFRASTRUCTURE

This section describes the avoidance and minimisation outcomes resulting from the processes described in Section 14.4.1 to design the urban and industrial development, intensive plant agriculture and infrastructure within urban capable land, and justifies the location of the urban capable land.

Avoidance outcomes are described in relation to:

- Serious and irreversible impact entities
- Prescribed impacts
- Native vegetation, including high condition native vegetation
- TECs
- Species potential habitat
- Important populations
- Areas important for connectivity

Avoidance outcomes are shown in Figure 14-1 to Figure 14-4.

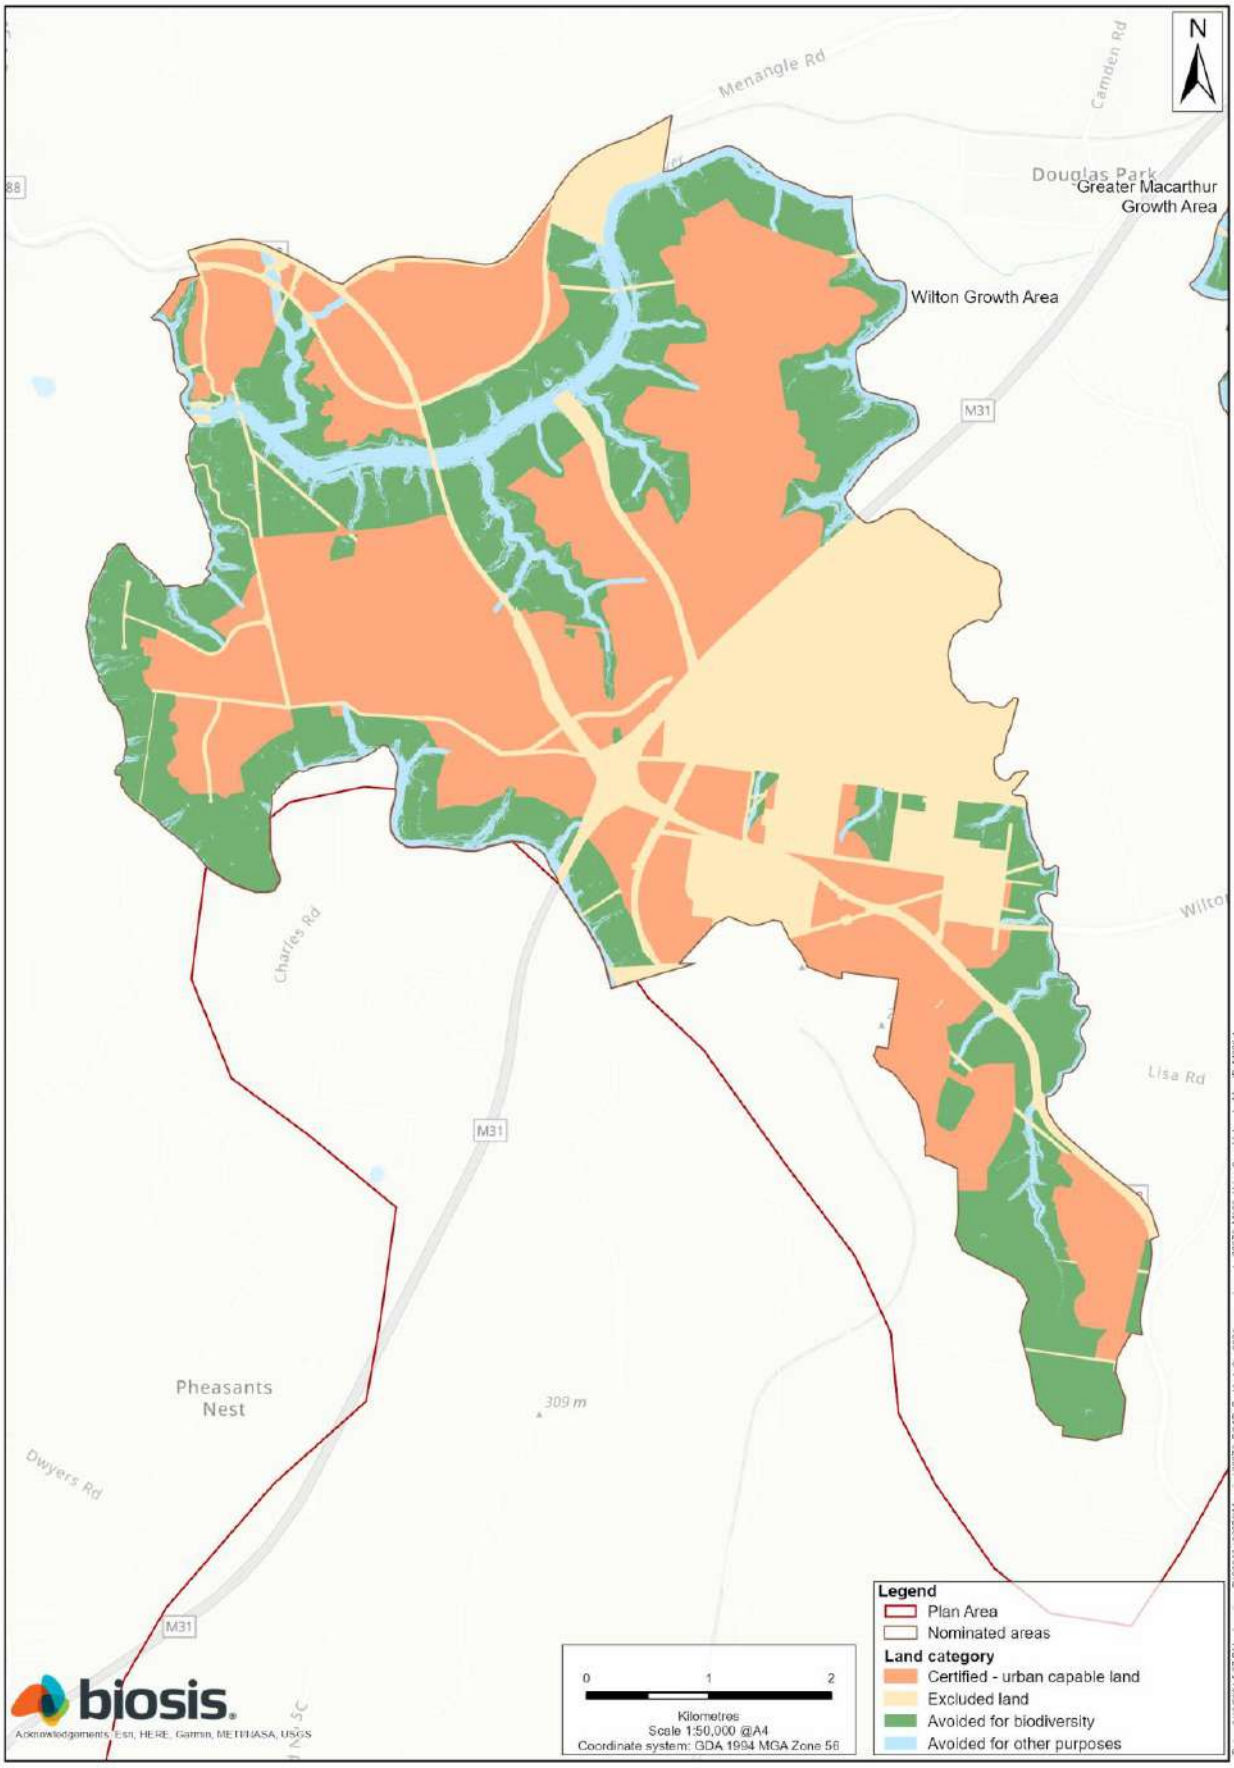


Figure 14-1: Avoidance outcomes – Wilton

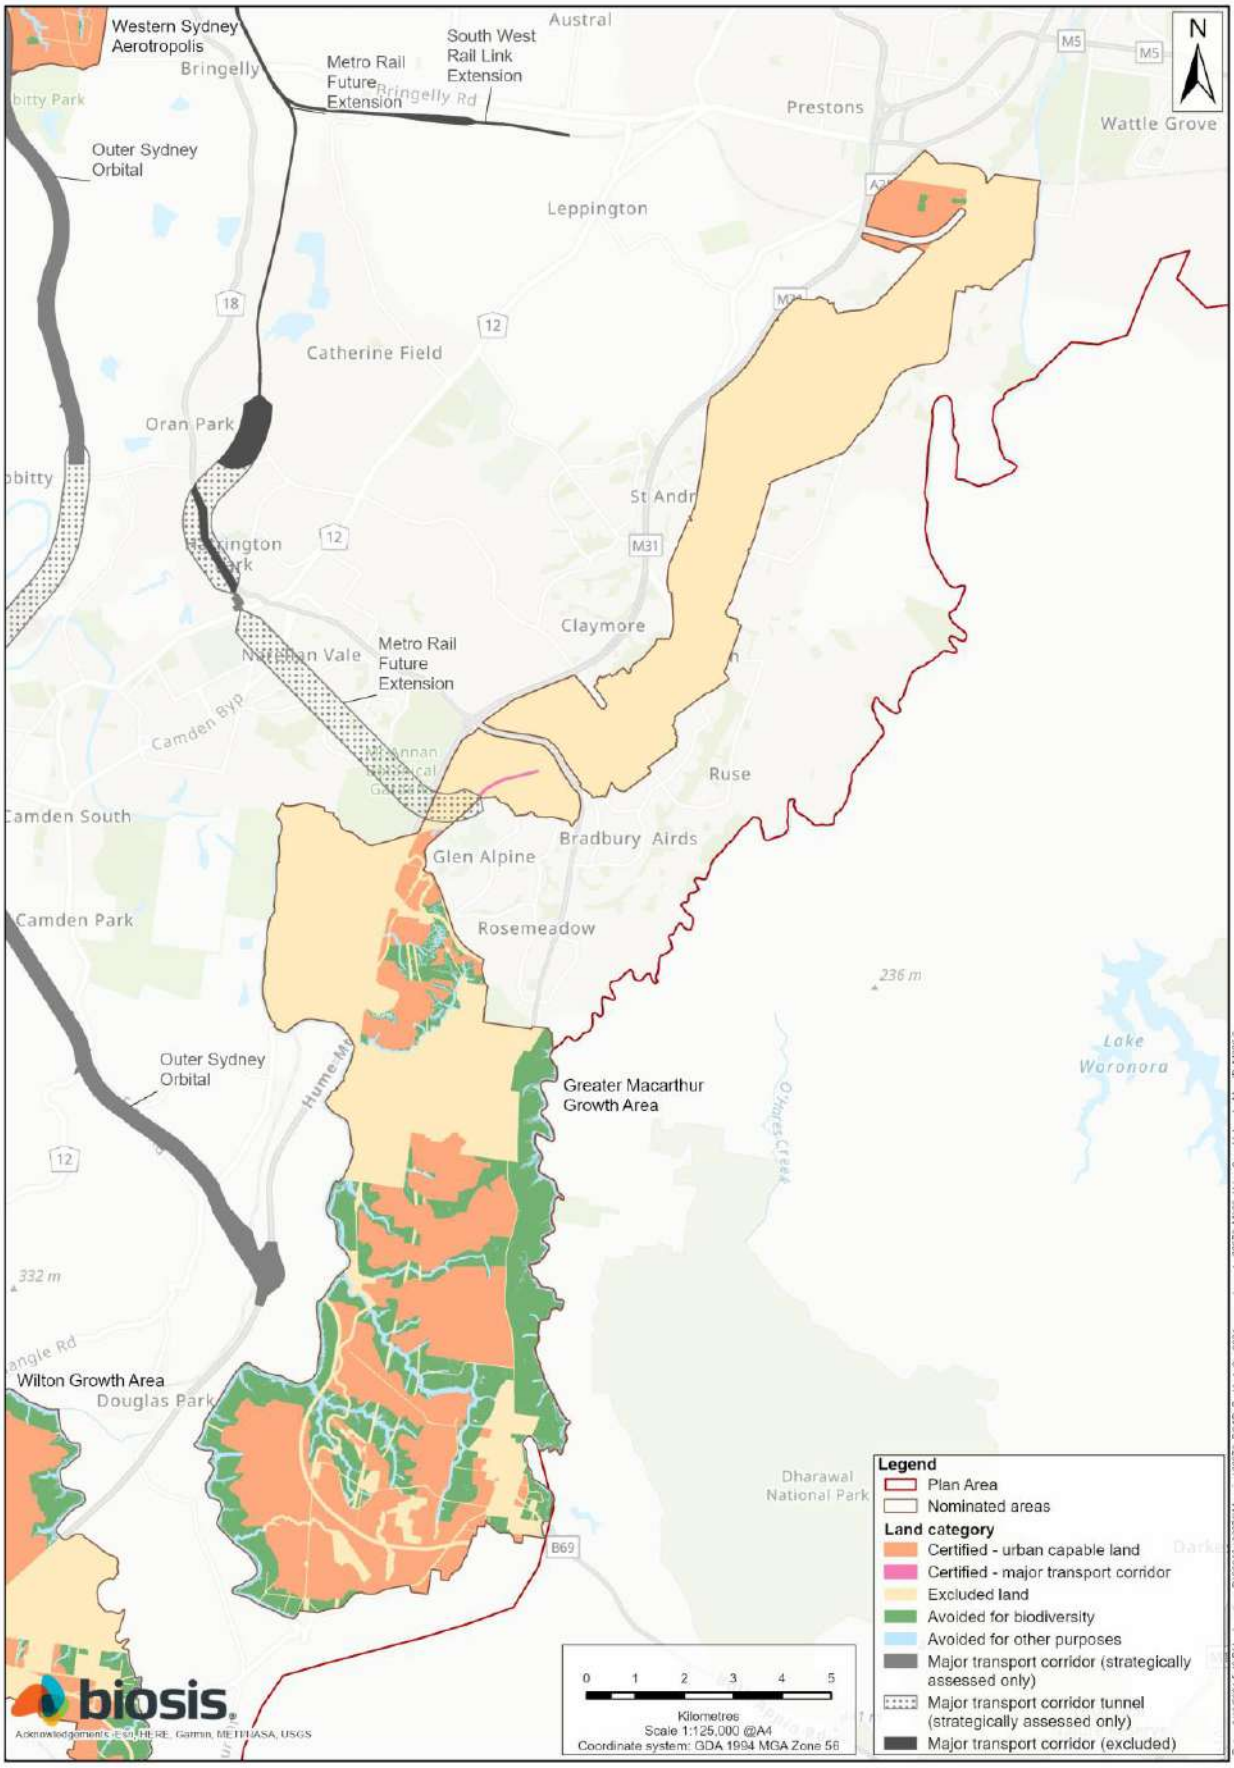

Figure 14-2: Avoidance outcomes – GMAC

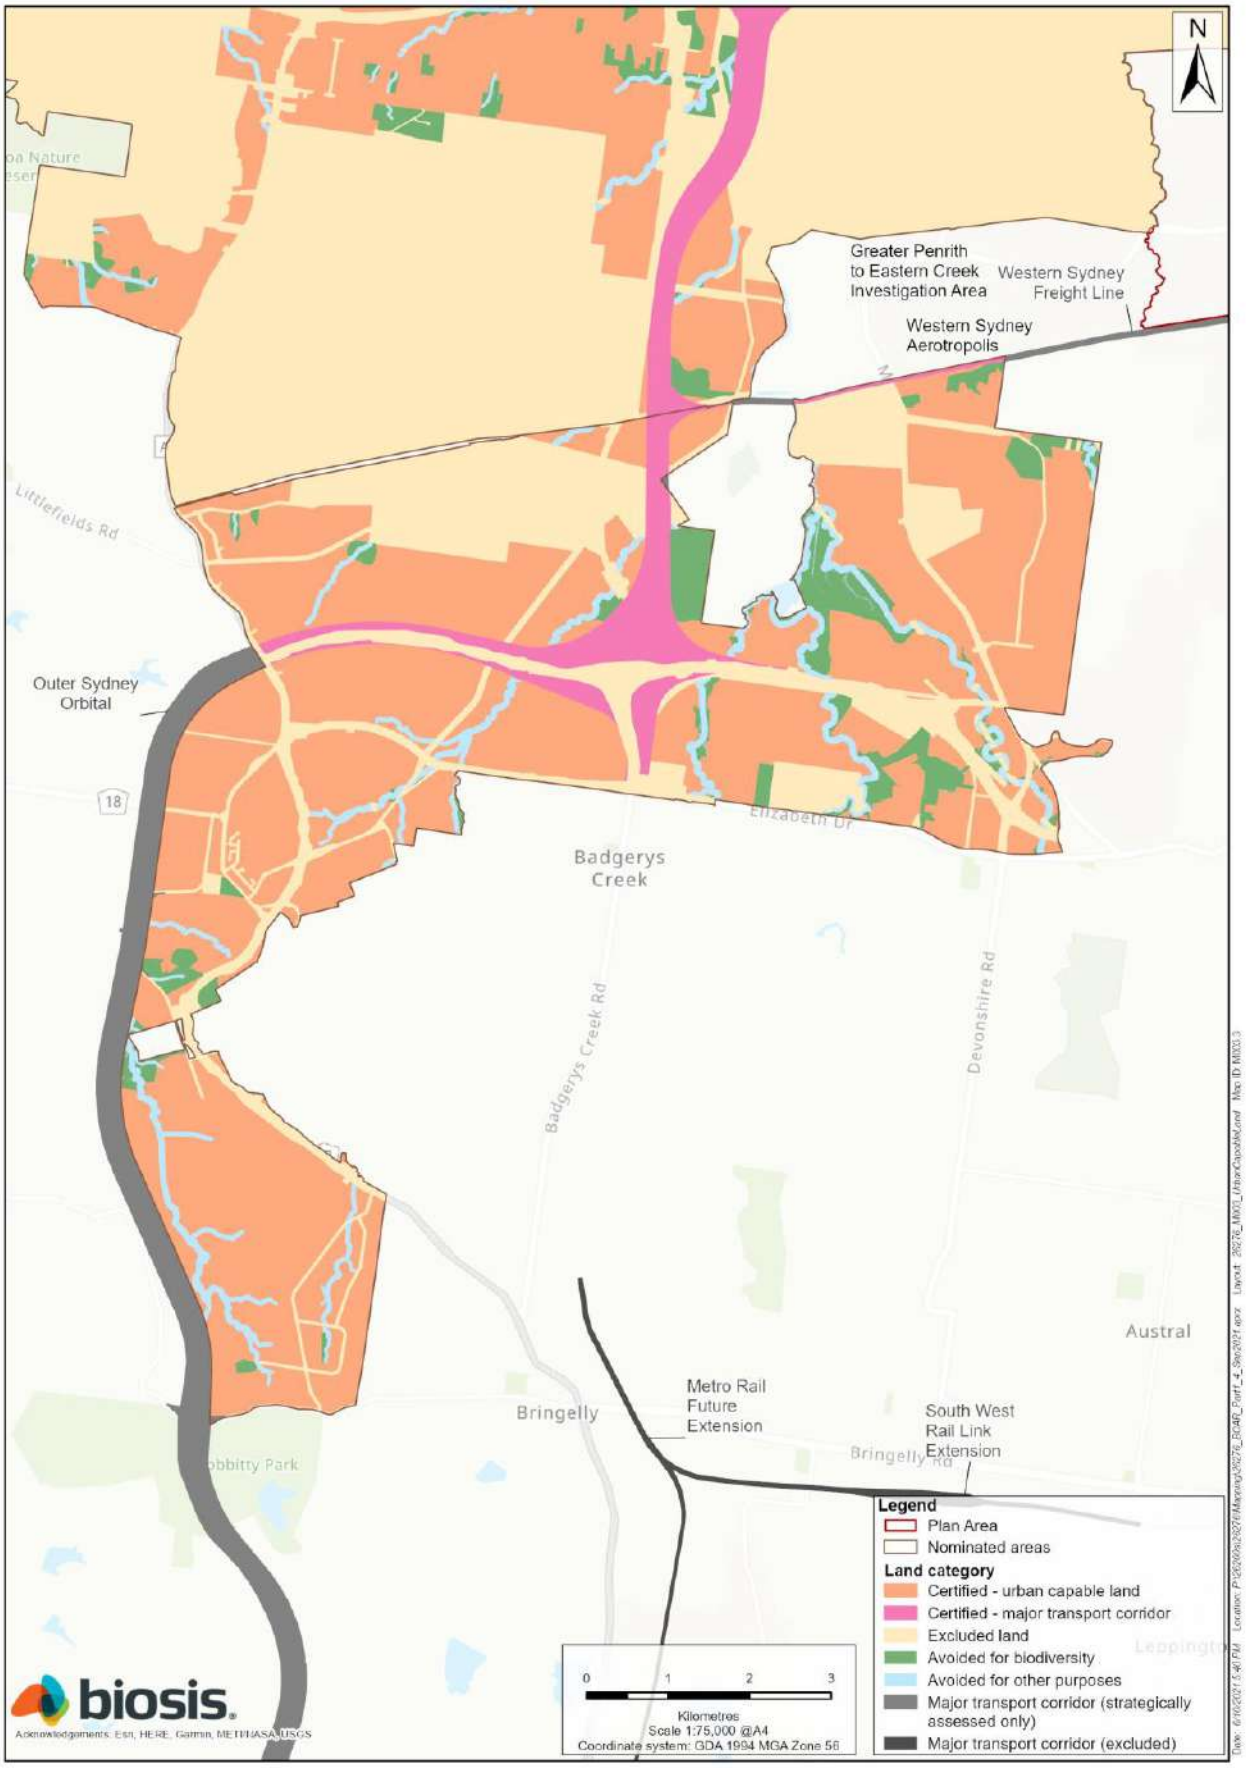

Figure 14-3: Avoidance outcomes – WSA

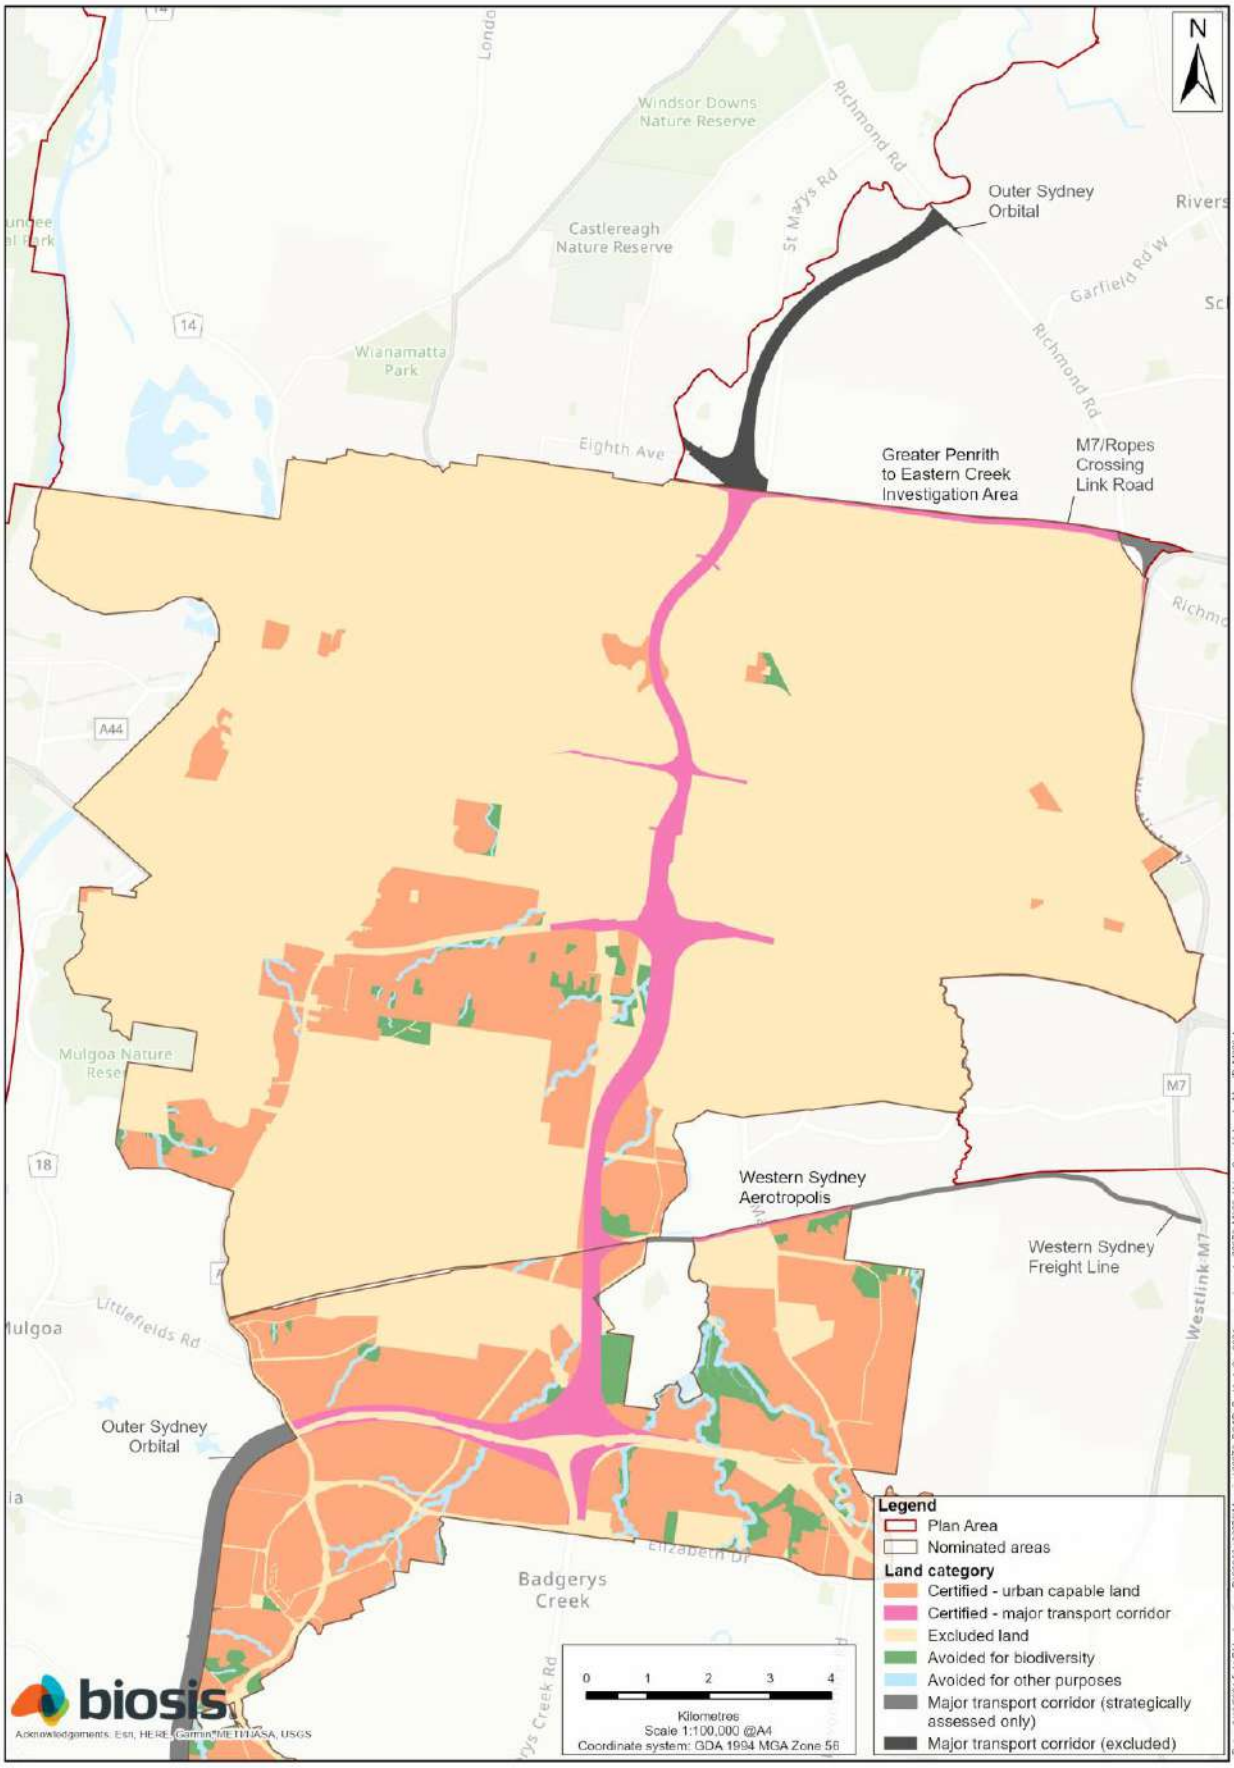

Figure 14-4: Avoidance outcomes – GPEC

SERIOUS AND IRREVERSIBLE IMPACT ENTITIES

The NSW and Commonwealth-listed SAII entities that may be subject to serious and irreversible impacts and that are potentially impacted by the development under the Plan are:

- TECs:
  - Cooks River/Castlereagh Ironbark Forest (NSW and Cth listed)
  - Cumberland Plain Woodland (NSW listed)/Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest (Cth listed)
  - Shale Sandstone Transition Forest (NSW and Cth listed)
- Flora:
  - *Allocasuarina glareicola* (NSW and Cth listed)
  - *Hibbertia fumana* (NSW listed)
  - *Melaleuca deanei* (NSW and Cth listed)
  - *Micromyrtus minutiflora* (NSW and Cth listed)
- Fauna:
  - Green and Golden Bell Frog (NSW and Cth listed)
  - Large-eared Pied Bat (NSW and Cth listed)
  - Little Eagle (NSW listed)
  - Red-crowned Toadlet (NSW listed)
  - Square-tailed Kite (NSW listed)
  - Swift Parrot (NSW and Cth listed)
  - White-bellied Sea-Eagle (NSW listed)

Table 14-4 and Table 14-5 summarise the avoidance outcomes for each SAII entity within the nominated areas. Avoidance outcomes are discussed in more detail in Chapter 25 for NSW-listed SAII entities and in Chapter 31 for Commonwealth-listed TECs and Chapters 29 and 30 for Commonwealth-listed species.

Avoidance effort for SAII entities has generally focused on TECs and habitat in higher condition (see Box 1 and Table 14-4 and Table 14-5) and/or of higher long-term viability (see Chapter 31). In many cases, impacts to larger patches are avoided. Where these impacts do occur, they are often on the edges of larger, contiguous patches associated with waterways and gullies and gorges, which minimises fragmentation and impacts on habitat connectivity, particularly in Wilton and GMAC (see Chapter 25 and Chapters 29 to 31 for more details).

Despite this overall conclusion, for some SAII entities, about half or less of the TEC or potential species habitat was avoided and residual impacts remain. This includes:

- Cumberland Plain Woodland
- Cooks River/ Castlereagh Ironbark Forest
- *Allocasuarina glareicola* and *Micromyrtus minutiflora*
- Green and Golden Bell Frog
- Swift Parrot

For these TECs, the scale of impacts is not substantial when considering the extent of these TECs across the Plan Area and the majority of intact condition and/or higher long-term viability TECs has generally been avoided (see Chapter 31). The offsets proposed by the Plan for these TECs (Commitment 8) will substantially increase the level of protection of these TECs in the Plan Area and address key threats identified in BioNet profiles and Conservation Advices.

For *Allocasuarina glareicola* and *Micromyrtus minutiflora* there are no impacts to records or important populations of the species (for each species, one important population occurs on excluded lands and will not be impacted).

While there will be direct impacts to small areas of Green and Golden Bell Frog habitat in GPEC, recent surveys along Ropes Creek indicate a population does not exist in that locality (see Supporting Document I).

For the Swift Parrot, the Plan provides a commitment (Commitment 9) to secure offsets of 100 ha of important habitat for the species to address residual impacts. The Plan also includes a range of other measures to mitigate risks to the species and increase its protection within the Plan area.

Table 14-4: Avoidance outcomes for SAII TECs within the nominated areas

SAII entity	Listing	Summary of TEC avoidance within nominated areas (without excluded lands)				Comment on avoidance outcomes within the nominated areas
		Total in nominated areas (ha)	Total avoided (ha / %)	Avoided for bio. reasons (ha / %)	Avoided for other reasons (ha / %)	
Cooks River/ Castlereagh Ironbark Forest	NSW	63.4 ha	25.8 ha / 40.7%	25.7 ha / 40.5%	0.2 ha / 0.2%	Between 40 - 45% of the TEC has been avoided For the NSW-listed TEC, of the 34.9 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (18.9 ha or 54.2%) has been avoided (see Chapter 25) For the Commonwealth-listed TEC, of the 34.6 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (18.9 ha or 54.6%) has been avoided (see Chapter 31)
	Cth	55.6 ha	24.7 ha / 44.5%	24.6 ha / 44.3%	0.1 ha / 0.2%	
Cumberland Plain Woodland	NSW	1,252.8 ha	321.3 ha / 25.6%	269.9 ha / 21.5%	51.4 ha / 4.1%	Between 25 - 45% of the TEC has been avoided For the NSW-listed TEC, of the 89.4 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (57.9 ha or 64.8%) has been avoided (see Chapter 25) For the Commonwealth-listed TEC, of the 32 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (22.3 ha or 69.6%) has been avoided (see Chapter 31)
	Cth	247.2 ha	111.5 ha / 45.1%	85.9 ha / 34.8%	25.6 ha / 10.3%	
Shale Sandstone Transition Forest	NSW	2,640.2 ha	2,180.5 ha / 82.6%	1,929.2 ha / 73.1%	251.3 ha / 9.5%	Between 81% - 91% of the TEC has been avoided For the NSW-listed TEC, of the 1,492.6 ha of intact condition TEC within the nominated areas (not including excluded land), the vast majority (1,446.8 ha or 96.9%) has been avoided For the Commonwealth-listed TEC, of the 1,485 ha of intact condition and 1,362.1 ha of high viability TEC within the nominated areas (not including excluded land), 1,437 ha of intact condition (or 97.1%) and 1,330.6 ha of high viability (or 97.7%) TEC, have been avoided Commitment 2.1 limits the cumulative direct impacts over the life of the Plan from essential infrastructure to this TEC
	Cth	2,197.4 ha	2,016.7 ha / 91.8%	1,769.1 ha / 80.5%	247.6 ha / 11.3%	

Table 14-5: Avoidance outcomes for SAII flora and fauna within the nominated areas

SAII entity	Summary of habitat avoidance (without excluded lands)				Comment on avoidance outcomes
	Total in nominated areas (ha)	**Total avoided (ha / %)**	**Avoided for bio. reasons (ha / %)**	**Avoided for other reasons (ha / %)**	
Flora					
Allocasuarina glareicola	32.3 ha	14.9 ha / 46.1%	14.8 ha / 45.7%	0.1 ha / 0.3%	About half the potential habitat has been avoided There are no impacts to records or important populations of the species (one important population occurs on excluded lands and will not be impacted)
Hibbertia fumana	1,299 ha	1,225.3 ha / 94.3%	1,083.7 ha / 83.4%	141.6 ha / 10.9%	Almost all potential habitat has been avoided There are no impacts to records of the species
Melaleuca deanei	1,750.3 ha	1,644.1 ha / 93.9%	1,545.2 ha / 88.3%	98.9 ha / 5.6%	Almost all potential habitat has been avoided There are no impacts to records of the species
Micromyrtus minutiflora	69 ha	37.3 ha / 54%	37.1 ha / 53.7%	0.2 ha / 0.3%	Over half the potential habitat has been avoided There are no impacts to records or important populations of the species (one important population occurs on excluded lands and will not be impacted)
Fauna					
Green and Golden Bell Frog	24.6 ha	11.3 ha / 45.8%	11.2 ha / 45.7%	<0.1 ha / 0.1%	About half the potential habitat has been avoided. It is important to note that much of the potential habitat mapped comprises existing urban areas (houses and roads), as the mapping was done by applying a buffer to records along Ropes Creek (see Chapter 25) There will be direct impacts to potential habitat in GPEC. However, recent surveys along Ropes Creek indicate a population does not exist in this locality
Large-eared Pied Bat*	882.2 ha	876.5 ha / 99.3%	452 ha / 51.2%	424.5 ha / 48.1%	Almost all potential breeding habitat has been avoided An important population has been partially avoided. Population 424 occurs as a single important population across the Plan Area and surrounds. The majority of records occur outside of nominated areas. Nine records occur within excluded lands and 2 records are located on avoided lands within central GMAC
Little Eagle*	2,935.5 ha	2,907.3 ha / 99%	2,237.5 ha / 76.2%	669.8 ha / 22.8%	Almost all potential breeding habitat has been avoided There are no impacts to known breeding sites (stick nests)

SAII entity	Summary of habitat avoidance (without excluded lands)				Comment on avoidance outcomes
	Total in nominated areas (ha)	**Total avoided (ha / %)**	**Avoided for bio. reasons (ha / %)**	**Avoided for other reasons (ha / %)**	
Red-crowned Toadlet	869 ha	859.7 ha / 98.9%	645.1 ha / 74.2%	214.6 ha / 24.7%	Almost all potential habitat has been avoided There are no impacts to records of the species
Square-tailed Kite*	2,919.2 ha	2,874.6 ha / 98.5%	2,220.2 ha / 76.1%	654.4 ha / 22.4%	Almost all potential breeding habitat has been avoided There are no impacts to known breeding sites (stick nests)
Swift Parrot	83.7 ha important habitat	40.4 ha / 48%	19.9 ha / 23.8%	20.6 ha / 24.6%	Approximately half of important habitat has been avoided No avoidance of potential important areas has occurred, although it is recognised that only a small area of potential important areas is located within the nominated areas Approximately 75 per cent of potential foraging habitat for the species has been avoided There are not impacts to breeding areas as the species breeds in Tasmania The Plan includes a commitment (Commitment 9) to secure 4,410 ha of potential foraging habitat for the Swift Parrot, including 100 ha of important habitat to offset residual impacts
	2.8 ha potential important areas	0 ha / 0% potential important areas	0 ha / 0% potential important areas	0 ha / 0% potential important areas	
	4,514.3 ha potential foraging habitat	3,414.6 ha / 75.6% potential foraging habitat	2,568.8 ha / 56.9% potential foraging habitat	845.8 ha / 18.7% potential foraging habitat	
White-bellied Sea Eagle*	1,616.6 ha	1,598.9 ha / 98.9%	1,031.8 ha / 63.8%	567.2 ha / 35.1%	Almost all potential breeding habitat has been avoided There are no impacts to known breeding sites (stick nests)

*Impacts relate to potential breeding habitat only

PRESCRIBED IMPACTS

The following prescribed impact types are relevant to the development:

- Karst, caves, crevices, cliffs, and other geological features of significance
- Rocks
- Human-made structures
- Non-native vegetation
- Habitat connectivity and movement
- Water bodies and hydrological processes
- Vehicle strikes

Avoidance and minimisation of prescribed impacts is summarised in Table 14-6. Further details about avoidance outcomes are provided in the assessment of prescribed impacts in Chapter 24.

Table 14-6: Avoidance outcomes for prescribed impacts within the nominated areas

Prescribed impact	Comment on avoidance outcomes
Karst, caves crevices, cliffs, and other geological features of significance	Most areas where karst, caves, crevices, cliffs, and other geological features are likely to occur have been avoided and do not occur within urban capable land or major transport corridors
Rocks	Areas where rocks are most likely to occur, particularly in Wilton and GMAC, are on the edges of the nominated areas and in the gully lines where the underlying sandstone is exposed. These areas are generally steep and unsuitable for urban development and have generally been avoided. The relevant species associated with rocky areas – Broad-headed Snake and Red-crowned Toadlet – are generally associated with rocky areas in native vegetation. Approximately 67.2 per cent of native vegetation, including 95.2 per cent of intact condition vegetation, has been avoided in the nominated areas (not including excluded land)
Human-made structures	Human-made structures are likely to occur throughout each of the nominated areas and it was not possible to determine avoidance outcomes for human-made structures. The Plan includes several specific mitigation measures that will avoid and minimise impacts to species identified at risk from this prescribed impact (micro-bat species)
Non-native vegetation	The avoidance criteria included prioritising avoidance of known habitat for species as indicated by BioNet records or surveys undertaken for the project, including any relevant areas of non-native vegetation where species records occur. Only very small amounts of non-native vegetation comprising suitable habitat for flora species associated with non-native vegetation will be impacted. While large areas of non-native vegetation will be impacted that may affect several bats and bird species, these species are generally more reliant on native vegetation, which was appropriately the focus of avoidance effort
Habitat connectivity and movement	See section 'Areas important for connectivity' below
Water bodies and hydrological processes	Urban capable land has avoided riparian corridors along waterways that are likely to be the preferred movement and foraging habitat for many of the species associated with water bodies and this will also minimise impacts to hydrological processes
Vehicle strikes	The Plan includes a range of commitments and actions, as well as specific mitigation measures in Appendix E of the Plan, to avoid the risk of vehicle strike through mitigation. This includes a range of measures specific to Koala. These measures are expected to adequately address the risk of vehicle strikes on species associated with this prescribed impact

NATIVE VEGETATION

Of the 5,352.4 ha of native vegetation occurring (not including excluded land) within the nominated areas:

- 2,714.4 ha (50.7 per cent) has been avoided for biodiversity purposes (as per the BAM definition)
- An additional 884.4 ha (16.5 per cent) has been avoided for other purposes and is not directly impacted by the Plan

Section 8.1.1.3 (b) of the BAM specifies that impacts can be avoided and minimised by locating development in areas where native vegetation is in the poorest condition, or by avoiding the highest condition native vegetation. For the purposes of this assessment high condition has been defined as vegetation mapped in the 'intact' condition state.

Table 14-7 indicates that the vast majority of the urban capable land for the nominated areas has been located in poorer condition native vegetation and avoided areas with the highest (intact) condition.

Of the high condition (intact) native vegetation in the nominated areas (2,398.5 ha, not including excluded lands):

- 1,630.5 ha (or 67.9 per cent) has been avoided for biodiversity purposes
- A total of 2,283.5 ha (or 95.2 per cent) has been avoided

Avoidance outcomes of intact native vegetation for GPEC are lower than for other nominated areas. This is due to:

- The impacts of the transport corridors – the OSO within GPEC directly impacts about 37.6 ha of intact native vegetation (65.9 per cent of total area of intact vegetation in GPEC, not including excluded lands), while the urban capable land directly impacts about 1.1 ha of intact vegetation. It is important to note that avoidance within the transport corridors has not yet occurred (see section 14.4) and it is likely that further avoidance of intact native vegetation within the OSO footprint will occur during strategic planning and detailed design
- A relatively small urban capable land area within a nominated area that is largely already developed for urban purposes, meaning the opportunities for avoidance across the nominated area is generally more constrained

Table 14-7: Avoidance of high condition (intact) native vegetation in nominated areas

THREATENED ECOLOGICAL COMMUNITIES

Section 8.1.1.3 (c) of the BAM specifies that impacts can be avoided and minimised by locating proposed development in areas that avoid critically endangered and endangered TECs.

Table 14-8 and Table 14-9 show avoidance and minimisation outcomes for each NSW-listed TEC and Commonwealth-listed TEC for each condition category across all the nominated areas.

Table 14-10 and Table 14-11 show avoidance and minimisation outcomes aggregated across critically endangered and endangered NSW-listed TECs and Commonwealth-listed TECs for each condition category within each nominated area.

The tables indicated that:

- The NSW-listed or Commonwealth-listed TECs with the largest avoidance achieved (per cent total avoided) are:
  - Moist Shale Woodland in the Sydney Basin Bioregion in good (intact) or moderate (thinned) condition
  - Shale Sandstone Transition Forest of the Sydney Basin Bioregion in good (intact) or moderate (thinned) condition
  - Swamp Oak Floodplain Forest of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions in good (intact) or moderate (thinned) condition
- The NSW-listed or Commonwealth-listed TECs with the least avoidance achieved (per cent total avoided) are:
  - Freshwater Wetlands on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions in moderate (thinned) or poor (scattered trees) condition
  - Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion in moderate (thinned) or poor (scattered trees) condition
  - Cumberland Plain Woodland in the Sydney Basin Bioregion in moderate (thinned) or poor (scattered trees) condition
- Of the 4,620.7 ha of critically endangered and endangered NSW-listed TECs (not including excluded land) 51.75 per cent has been avoided for biodiversity purposes, and a total of 62.1 per cent has been avoided
- Of the 2,811.1 ha of critically endangered and endangered Commonwealth-listed TECs (not including excluded land) 69.3 per cent has been avoided for biodiversity purposes, and a total of 83.3 per cent has been avoided

Not including excluded lands

SPECIES POTENTIAL HABITAT

Section 8.1.1.3(c) of the BAM specifies that the proposed development should avoid areas of habitat for species with a high biodiversity risk weighting. Risk-weightings are identified by EES for each species and used in credit calculations as part of assessing the impacts of a development on each species. Risk-weightings are based on the combination of the sensitivity of the species to loss at the development site, and sensitivity of the species to potential gain at an offset site.

Table 14-12 sets out the amounts of potential habitat avoided for NSW-listed candidate species credit species (SCS) with a high or very high biodiversity risk weighting in the nominated areas.

The table indicates that within the nominated areas the average avoidance of potential habitat is:

- 69.9 per cent for the four candidate SCS with a very high-risk weighting (not including excluded lands) (*Allocasuarina glareicola*, *Hibbertia fumana, Lathamus discolor* and *Chalinolobus dwyeri*)
- 77.1 per cent for the candidate SCS with a high-risk weighting (not including excluded lands)

Avoidance outcomes for each Commonwealth-listed species are further described in Chapters 29 and 30.

** Important habitat

IMPORTANT POPULATIONS

Table 14-13 summarises the avoidance outcomes for important populations for each Commonwealth-listed species.

In total 19 species have mapped important populations within the nominated areas, of which the important populations identified for 13 species are not entirely included on excluded land. Of 13 species with important populations identified outside excluded land 11 have important populations represented (either wholly or partially) on land avoided for biodiversity purposes. It is important to note that in some cases, records that form part of the important population may be located across several land categories (urban capable land, excluded land, or avoided land).

The avoidance outcomes and extent of direct impacts under the Plan to each important population are further described in the assessments for each Commonwealth-listed species in Chapters 29 and 30. The location of each important population is also shown in the habitat maps for each species provided in those chapters.

Table 14-13: Summary of avoidance of important populations for Commonwealth-listed species

Scientific name	Important populations in nominated areas			Important populations avoided			Location of avoided population records

Not including excluded lands

AREAS IMPORTANT FOR CONNECTIVITY

Section 8.1.1.3(d) of the BAM specifies that the development should avoid areas important for maintaining habitat connectivity. BIO Map core areas and corridors (OEH, 2015) provide a surrogate measure of habitat connectivity and a useful approach to evaluating avoidance outcomes in terms of connectivity.

The purpose of BIO Map is to identify areas on the Cumberland subregion where investment in conservation actions will have maximum benefit. It is acknowledged that BIO Map is not intended to be used for land-use planning, as it does not identify all significant vegetation. However, BIO Map core areas represent the habitat most likely to support species persistence and the maintenance of interactions between species and landscape scale ecological processes, and BIO Map corridors play a crucial role in maintaining connectivity between species populations.

Table 14-14 and Table 14-15 set out the amounts of Bio Map core areas and corridors avoided in the nominated areas. The tables indicate that of the core areas and corridors within the nominated areas (not including excluded land):

- 68.8 per cent of core areas have been avoided for biodiversity purposes, and a total of 88.7 per cent has been avoided
- 54.6 per cent of corridors have been avoided for biodiversity purposes, and a total of 83.7 per cent has been avoided

In relation to Koala, all primary and secondary Koala corridors have been avoided in Wilton and GMAC. Following public exhibition, more land was avoided along the Nepean River in Wilton and the Nepean River and Menangle Creek in GMAC to protect the integrity and functionality of the Koala corridors in these areas, and to ensure that the corridors are on average 390-425 m wide (as recommended by the NSW Chief Scientist)

As described above in the section 'Native vegetation', avoidance outcomes of intact native vegetation for GPEC are lower than for other nominated areas. Despite this, it is considered that development under the Plan will generally avoid the areas that are most likely to be important for habitat connectivity within GPEC. The majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impacts occur:

- Within Wianamatta Regional Park where the OSO severs the eastern part of the regional park that is connected to Ropes Creek with the western part of the park
- Along Wianamatta (South Creek) where the OSO directly impacts the riparian corridor and severs the narrow connection along the corridor that links Wianamatta Regional Park and Orchard Hills

The other areas of potential habitat connectivity within GPEC comprise connected patches of vegetation (within 100 m of another patch) or isolated patches of vegetation (greater than 100 m from another patch) (there are no other areas of contiguous native vegetation forming habitat corridors outside Bio Map core areas/corridors). The development will result in the clearing of many small patches of connected vegetation, as well as the edges of several larger connected patches. This may reduce habitat connectivity across the area for more mobile species, such as bats and birds. Impacts to larger connected patches will reduce the size of the patches but will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas.

CONCLUSION

The avoidance and minimisation process described in Section 14.4.1 to design the urban and industrial development, intensive plant agriculture and infrastructure within urban capable land has led to substantial avoidance outcomes and is considered to be consistent with the guidance under the BAM and requirements of the ToR.

The avoidance process was detailed and robust and based on the best available data on biodiversity values. The urban capable land was located by establishing a planning process that took into account biodiversity values and prioritised the avoidance of high biodiversity values through a set of criteria.

Where biodiversity priorities were inconsistent with urban development priorities, the decision-making process sought to balance these priorities. This was achieved through negotiations on options between the Department's strategic assessment team and the Department's planning team to:

- Explain and justify urban development and avoidance priorities
- Explore alternative development locations to achieve the urban development priorities
- Make decisions on final urban capable land boundaries (see Box 2)

The process to avoid and minimise impacts has led to substantial avoidance outcomes for native vegetation, high (intact) condition native vegetation, the majority of Commonwealth-listed and NSW-listed TECs, including the most endangered TECs and potential habitat for species with a very high and high biodiversity risk weighting (>3). Within the nominated areas, total avoidance for biodiversity and other purposes (not including excluded lands) includes:

- Approximately 67.2 per cent of all native vegetation, including 95.2 per cent of intact condition vegetation
- Approximately 83.3 per cent of critically endangered and endangered Commonwealth-listed TECs and 62.1 per cent of critically endangered and endangered NSW-listed TECs
- An average of 69.9 per cent of potential habitat for four species with a very high biodiversity risk weighting (>3), and an average of 77.1 per cent of potential habitat for 31 species with a high biodiversity risk weighting (≥2)
- Of 13 species with important populations identified outside excluded land 11 have important populations represented (either wholly or partially) on land avoided for biodiversity purposes
- Approximately 88.7 per cent of Bio Map core areas and 83.7 per cent of Bio Map corridors

The avoidance outcomes of the Plan are supported by several commitments that ensure:

- The amount of avoidance to be achieved under the Plan is certain – the Plan commits to avoiding 4,795 hectares of high biodiversity value areas within avoided land
- Avoided land is protected and the impacts of any future urban development proposed on avoided land is minimised through development controls under the SEPP (Strategic Conservation Planning) and the preparation of a Ministerial Direction under section 9.1 of the EP&A Act
- Asset protection zones will be located wholly within certified - urban capable land
- The impacts of any proposed development on avoided land will be monitored

14.5.2 MAJOR TRANSPORT CORRIDORS

Avoidance and minimisation of impacts from the major transport corridors is being undertaken in two stages:

- Strategic planning to determine the locations of the major transport corridors
- Future detailed design to determine the location of the infrastructure within the transport corridor footprint

The strategic planning process to determine the location of the major transport corridors is considered to have resulted in adequate avoidance and minimisation outcomes. The process involved a detailed set of steps that considered environmental constraints, including biodiversity values, alongside other infrastructure, social and economic outcomes to balance overall planning outcomes. In making decisions on corridor selection, infrastructure agencies undertake a constraints analysis and multi-criteria comparison of options. Key factors considered included:

- Proximity to current and planned locations of employment
- The cost of infrastructure provision including roads, water, sewerage, public transport, schools, and health facilities
- The economic and social cost to communities of having poor access to employment and services, including transport

- Environmental constraints, including biodiversity values

In some cases, infrastructure, social and economic considerations outweighed biodiversity considerations, including in relation to the location of the OSO through Wianamatta Regional Park. It is important to note that this decision was undertaken in close consultation with EES.

Commitment 3 and Commitment 4 will ensure the future detailed design to determine the location of the infrastructure within the transport corridors will lead to additional avoidance and minimisation outcomes for biodiversity values. These commitments are considered adequate to ensure the corridors avoid and minimise the risk of unacceptable impacts on biodiversity values. These commitments will ensure:

- For the major transport corridors (strategically assessed only) outside the nominated areas, impacts are avoided and minimised in accordance with the NSW State Significant Infrastructure (or equivalent) approvals process and BAM under the BC Act (or equivalent). The assessment process is considered to be robust as it will be undertaken under NSW planning and assessment laws current at the time the development is proposed
- Avoidance outcomes are achieved consistent with the Plan's 'avoidance criteria' (see Box 1) or are assessed and determined in accordance with the BAM (for the major transport corridors outside the nominated areas)
- Impacts to known key biodiversity values within the corridors are avoided and minimised where possible, including specific species and habitat, and/or specific locations of high biodiversity value
- Avoidance of biodiversity values as well as the costs of offsets is taken into account in the evaluation of the route options (e.g. multi-criteria analysis) during the planning phase of each project
- Governance arrangements are in place to ensure avoidance outcomes achieved and the residual impacts of the infrastructure within the transport corridor footprints are reported transparently to DPIE

14.5.3 ESSENTIAL INFRASTRUCTURE

A description of the avoidance requirements and process for essential infrastructure is provided in Chapter 37. A summary of the avoidance outcomes for essential infrastructure is provided below.

The guidelines for essential infrastructure development in Appendix A of the Plan and commitments under the Plan (Commitment 2.1 and 2.2) are considered adequate to ensure essential infrastructure avoids and minimises unacceptable impacts on biodiversity values in avoided land. These requirements will ensure:

- Only a limited amount of essential infrastructure development can occur within avoided land
- Each essential infrastructure project must consider environmental impacts under the EP&A Act, and apply an 'avoid, minimise and mitigate' process to strategic planning and detailed design
- The cumulative direct impacts to TECs identified at risk of impacts in the Assessment Report (see Chapter 37) are capped within each nominated area to levels that are considered acceptable
- Avoidance and minimisation of impacts to populations of species identified at risk of impacts in the Assessment Report (see Chapter 37) is given high priority
- Governance arrangements are in place to ensure the Department can appropriately monitor the outcomes

Furthermore, the impacts of each project will be assessed under the BC Act and BAM (where triggered under the Act), which requires an avoid, mitigate, and offset process to be applied to ensure outcomes are acceptable.

15 Managing indirect impacts

15.1 INTRODUCTION

The BAM and the Commonwealth ToR require indirect impacts to be identified and assessed.

Indirect impacts are any impacts that could adversely affect biodiversity values, such as native vegetation, TECs and threatened species habitat, beyond the urban capable land. Indirect impacts may also result from changes to land-use patterns, such as an increase in vehicular access and human activity.

This Chapter:

- Sets out the regulatory requirements for managing indirect impacts under the BAM and ToR
- Describes the approach applied to identify and assess indirect impacts
- Describes the indirect impacts relevant to the Plan, including their nature, extent, and duration
- Identifies the threatened species and TECs at risk of indirect impacts
- Describes the general mitigation measures and processes that will be implemented to address each indirect impact
- Assesses the potential indirect impacts on each species and TEC taking into account the general mitigation measures that will be implemented under the Plan, and identifies whether there are any residual indirect impacts
- Describes any additional species or TEC specific mitigation measures to address any residual indirect impacts
- Identifies the threat abatement plans under the EPBC Act relevant to the Plan and how they relate to the Plan

This Chapter also covers the assessment of indirect impacts on NSW-listed TECs and species as required under the BAM.

Detailed assessments of the potential indirect impacts on each Commonwealth-listed TEC and species, as well as other EPBC Act protected matters, are presented in the following chapters:

- Chapter 29 – Commonwealth-listed flora
- Chapter 30 – Commonwealth-listed fauna
- Chapter 31 – Commonwealth-listed TECs
- Chapter 32 – Migratory species
- Chapter 33 – Ramsar wetlands
- Chapter 34 – World and National Heritage
- Chapter 35 – Commonwealth Land

15.2 REGULATORY REQUIREMENTS

15.2.1 BC ACT REQUIREMENTS

Section 9 of the BAM requires the Assessment Report to assess the potential indirect impacts of the Plan on biodiversity values. The Assessment Report must:

- Describe the nature, extent, and duration of short-term and long-term impacts
- Identify the species and TECs likely to be affected
- Predict the consequences of the impacts for the bioregional persistence of the species and TECs
- Document mitigation measures proposed to manage impacts
- Identify any measures for which there is risk of failure
- Evaluate the risk and consequence of any residual impacts likely to remain after mitigation measures are applied
- Document any adaptive management strategy that is proposed (this is described in Chapter 16)

15.2.2 EPBC ACT REQUIREMENTS

Section 4.5 of the Commonwealth ToR requires the Assessment Report to consider potential indirect impacts on MNES and describe what mitigation will be implemented to reduce indirect impacts.

Section 5.3 of the ToR requires the Assessment Report to consider the likely effectiveness of the conservation measures under the Plan in protecting and managing MNES and any related risks and uncertainties.

15.3 APPROACH TO THE ASSESSMENT

The steps taken to assess indirect impacts involved:

Step 1: Identify the range of indirect impact types associated with the development and describe the nature, extent, and duration of each indirect impact type. This involved:

- Nature of impacts – qualitatively describe each indirect impact type, including cause and scope of the impact
- Extent of impacts – identify the general location and extent of indirect impacts
- Duration – identify whether the impacts are short-term or long-term

Step 2: Identify the species and TECs likely to be affected by each indirect impact within each nominated area and the transport corridors. All indirect impact types identified through Step 1 were considered. The relevance of an indirect impact type was determined by drawing on ecological and life history information in BioNet profiles, conservation advices, recovery plans, as well as species records and habitat maps prepared for this Assessment Report

Step 3: Describe the general mitigation measures and processes that will be implemented to mitigate indirect impacts

Step 4: Assess the potential indirect impacts on each species and TEC and identify any potential residual impacts. This was done taking into account:

- Likely presence/abundance of species/TEC and importance of the location at a local and regional scale
- Life history traits and susceptibility of the species/TEC to the indirect impact
- Location of the species/TEC relative to the likely extent of the indirect impact
- Amount and quality of un-impacted habitat remaining
- Levels of existing protection
- The effectiveness of the general mitigation measures and processes described through step 3

Step 5: Describe any additional specific mitigation measures needed to address potential residual indirect impacts identified through step 4 to particular species or TECs

15.4 NATURE, EXTENT AND DURATION OF INDIRECT IMPACTS

15.4.1 SUMMARY OF DEVELOPMENT UNDER THE PLAN

The types of development under the Plan that have the potential to cause indirect impacts on biodiversity values are described in detail in Part 2 and include:

- Urban and industrial development in the nominated areas
- Infrastructure in the nominated areas
- Intensive plant agriculture in the Agribusiness precinct in Western Sydney Aerotropolis
- Major transport corridors

URBAN AND INDUSTRIAL DEVELOPMENT

Urban and industrial development will occur within the urban capable land in the nominated areas. This development may include:

- Mixed residential, commercial, and industrial development
- Major town centres with a full range of shops, and public and private recreational facilities and services

- Social infrastructure such as education facilities, cultural facilities, childcare services, sports facilities, entertainment facilities, places of public worship, libraries, and community centres
- Essential services such as health facilities and emergency services facilities
- General industrial facilities such as retail outlets, manufacturing industries, training facilities, information and technology facilities, light industries, high-tech industries, material supply centres and distribution centres
- Supporting infrastructure for parks and public reserves (environmental facility, information and education facility, kiosk, recreation area, recreation facilities (outdoor), water recreation structure)
- Agribusiness, including businesses associated with the production, processing, marketing, and distribution of agricultural products
- Wholesale markets, including retail, accommodation, and large distribution centres, trading floor and associated infrastructure such as cold stores, ripening rooms, treatment facilities and waste management
- Advanced food manufacturing and logistics
- Warehouse, freight and logistics, including distribution centres, freight transport facilities and heavy industrial storage establishments and storage premises
- Airport and ancillary uses to support the delivery and operation of the new airport

INFRASTRUCTURE

Infrastructure development will predominantly be located within urban capable land and may include:

- Electricity transmission or distribution networks
- Gas pipelines
- Road or road infrastructure facilities, including public transport facilities
- Railways and rail infrastructure facilities
- Water reticulation systems, water storage facilities, water treatment facilities, or a water supply system
- Telecommunications facilities or telecommunication network
- Stormwater management system
- Resource recovery facility, waste disposal facility, waste or resource management facility and waste or resource transfer station
- Organic waste and composting facilities
- Koala exclusion fencing as described in the Strategic Conservation Planning SEPP
- Fauna crossings as described in the Strategic Conservation Planning SEPP.

INTENSIVE PLANT AGRICULTURE IN THE AGRIBUSINESS PRECINCT

The Agribusiness Precinct in WSA will provide for the movement and storage of agricultural commodities at the northern and western edges of the Western Sydney International (Nancy-Bird Walton) Airport. Development in this area may include the following:

- Intensive plant agriculture, including protective cropping structures used primarily for horticultural applications to control specific environmental conditions and facilitate high-quality, high-quantity production of a defined fruit, vegetable, or flower. Note: turf farms are prohibited under the Aerotropolis SEPP
- The cultivation of irrigated crops for commercial purposes (other than irrigated pasture or fodder crops)
- Horticulture and viticulture

MAJOR TRANSPORT CORRIDORS

Transport development includes all activities associated with the design, construction, and operation of major infrastructure corridors. These activities include, but are not limited to:

- Vegetation clearing
- Earthworks
- Utility works
- Landscaping

- Erosion and sediment control
- Laydown areas
- Road and rail construction
- Tunnel construction
- Construction of supporting infrastructure such as stations, car parks and pedestrian access
- Electricity infrastructure
- Site offices and access roads
- Dust and noise suppression
- Stormwater management (including detention basins, ponds, and dams)
- Vehicle and train movements
- Maintenance and upgrade activities
- Installation and maintenance of traffic control and safety infrastructure

15.4.2 IMPACTS ASSOCIATED WITH EACH DEVELOPMENT TYPE

Table 15-1 identifies each indirect impact type associated with each type of development under the Plan, and the nature, extent, and duration of the indirect impacts.

The nature, extent and duration of the impacts are described broadly. Due to the large scale of the development and the staging of construction precinct by precinct over the life of the Plan, it is not possible to be specific about the nature and extent of impacts in relation to specific vegetation zones at any particular location, or the exact timing of the development at any particular location. The approach taken is considered appropriate for assessment at a strategic scale.

The nature of each indirect impact type is described in more detail in Sections 15.4.3 to 15.4.12.

Table 15-1: Indirect impact types and nature, extent and duration of indirect impacts associated with the Plan

Indirect impact type	Development types relevant to the indirect impact				Nature of indirect impact	Extent/general location of indirect impact and/or high-risk areas	Duration of indirect impact
	Urban and industrial	Infrastructure	Intensive plant agriculture	Transport corridors			
Hydrological/ soil disturbance	✓	✓	✓	✓	Changes to surface water and groundwater flows and water quality due to development and infrastructure disrupting natural flows; the introduction of pollutants particularly associated with urban/agriculture; and soil erosion/disturbance associated with all development types	Waterways, wetlands, flood-prone areas within or downstream of development	Short term to long-term
Ground settling or subsidence				✓	Settlement/subsidence of ground in the vicinity of transport tunnels due to the tunnel void or groundwater removal, which may cause disturbance to the land surface	Land within or in vicinity of the transport tunnels	Long-term
Spread of infection/disease	✓	✓	✓	✓	Spread of pathogens from contaminated clothing and equipment or surface water runoff	Native vegetation and habitat retained within or adjacent to development	Likely long-term
Spread of weeds	✓	✓	✓	✓	Spread of invasive species due to edge effects, surface water run-off, or changed fire regimes	Native vegetation and habitat retained within or adjacent to development	Likely long-term
Predation/ competition by pest/domestic fauna	✓	✓	✓	✓	Increased predation and competition of species by pest/domestic fauna	Habitat retained within or adjacent to development including well-connected habitat corridors	Likely long-term

Indirect impact type	Development types relevant to the indirect impact				Nature of indirect impact	Extent/general location of indirect impact and/or high-risk areas	Duration of indirect impact
	Urban and industrial	Infrastructure	Intensive plant agriculture	Transport corridors			
Altered fire regimes	✓	✓	✓	✓	Altered fire regimes as a result of increased burns for asset protection, reduced ability to burn due to risk to surrounding urban areas or increased risk of unmanaged fires or accidental fires	Native vegetation and habitat retained within or immediately adjacent to development, particularly asset protection zones	Long-term
Disturbance from increased public access to natural areas	✓	✓			Trampling of species or habitat, removal of wood or bush rock, damage from mountain-biking and four-wheel driving	Publicly accessible natural areas retained within or immediately adjacent to development	Short term to permanent
Fauna mortality, displacement, and barriers to movement	✓	✓	✓	✓	Potential for mortality of threatened fauna species by vehicle strike and reduced movement and connectivity between habitat areas due to the introduction of new barriers	Habitat intersected by development that poses a barrier to movement or accessibility	Long-term
Fauna disturbance due to noise, dust, or light	✓	✓	✓	✓	Noise, dust, or light created by equipment during construction or by new structures or activities during operation	Habitat retained within or adjacent to development	Short-term to long-term
Inadvertent impacts on adjacent habitat or vegetation	✓	✓	✓	✓	Damage to adjacent habitat during construction activities or during ongoing management and use	Native vegetation and habitat immediately adjacent to development	Short-term to long-term

15.4.3 HYDROLOGICAL/SOIL DISTURBANCE

REDUCTION IN SURFACE WATER QUALITY AND CHANGES TO SURFACE WATER FLOWS

Development under the Plan may lead to changes to hydrology and water quality. This is primarily related to:

- Disruption to natural flows and processes
- New irrigation schemes and construction of dams for agricultural purposes
- Increase of hard surfaces leading to an increased volume of water entering downstream waterways
- Introduction of contaminants into surface water, such as nutrients, chemicals, and sediment from urban, agriculture and other development and land uses, including disturbance of soils/contaminated soils during construction

Changes to surface water quality and hydrology can impact a range of listed species and TECs. Species that rely on aquatic environments such as swamps and riparian corridors are particularly at risk from these types of impacts.

CHANGES TO GROUNDWATER

Development under the Plan may affect groundwater quality, including from salinity and contamination. This is primarily related to:

- Clearing for construction
- Construction works involving large excavations
- Use of groundwater for agricultural purposes
- Dewatering or structures buried below the water table, including groundwater removal from the tunnel voids associated with the transport corridor tunnels
- Diversion of surface water, including installation of buildings and hard surfaces

Changes to groundwater can affect groundwater-sensitive species and habitats and dependent ecosystems.

SOIL DISTURBANCE

Development under the Plan may cause soil erosion and sedimentation and disturbance to contaminated soils, which can lead to changes in water quality. This is primarily related to:

- Vegetation clearing for construction or planting
- Construction works involving large excavations
- The management of spoil during construction, particularly for the construction of the transport corridor tunnels

15.4.4 GROUND SETTLEMENT/SUBSIDENCE

Construction of the transport corridor tunnels involves the creation of a tunnel void and removal of groundwater from the void. This may cause ground settlement and subsidence to the land surface above and in the vicinity of the tunnel, causing disturbance to any biodiversity or other values in the affected area.

15.4.5 SPREAD OF INFECTION/DISEASE

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles, and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

Spread of infection/disease can affect species and have associated impacts on TECs.

Key threatening processes listed under the BC Act and EPBC Act relevant to this indirect impact type are:

- Infection of amphibians with chytrid fungus resulting in chytridiomycosis (EPBC Act)/infection of frogs by amphibian chytrid causing the disease chytridiomycosis (BC Act)

- Infection and dieback caused by the root-rot fungus *Phytophthora cinnamomi* (EPBC Act)/infection of native plants by *Phytophthora cinnamomi* (BC Act)
- Introduction and establishment of Exotic Rust Fungi of the order *Pucciniales pathogenic* on plants of the family *Myrtaceae* (BC Act)
- Novel biota and their impact on biodiversity (EPBC Act)
- Psittacine Circoviral (beak and feather) Disease affecting endangered psittacine species (EPBC Act/BC Act)

15.4.6 SPREAD OF WEEDS

Development under the Plan has the potential to increase the spread of invasive species and weeds. This is primarily related to:

- New environmental conditions at the edges of developments such as altered light levels, windspeed, and temperature, that may facilitate the spread of weeds
- Use of inappropriate species in landscaping and revegetation
- Accidental dispersal of weed seeds and plant material
- Altered fire regimes

Species are most susceptible to this threat where new urban growth or transport corridors occur adjacent to known populations or habitat. Weeds can reduce the viability of adjacent habitat or vegetation for listed species and TECs and can reduce the health of important habitat features. Invasive species of particular concern are:

- African lovegrass (*Eragrostis curvula*)
- African olive (*Olea europaea* subsp. *cuspidata*)
- Asparagus fern (*Asparagus aethiopicus*)
- Black nightshade (*Solanum nigrum)*
- Bridal creeper (*Asparagus asparagoides*)
- Buffalo grass (*Stenotaphrum secundatum*)
- Castor-oil plant (*Ricinus communis*)
- Coolatai Grass (*Hyparrhenia hirta*)
- Kikuyu grass (*Cenchrus clandestinus*)
- Lantana (*Lantana camara*)
- Long-leaf willow primrose (*Ludwigia longifolia*)
- Rhodes grass (*Chloris gayana*)
- Whisky grass (*Andropogon virginicus*)

Key threatening processes listed under the BC Act and EPBC Act relevant to this indirect impact type are:

- Invasion and establishment of exotic vines and scramblers (BC Act)
- Invasion, establishment and spread of Lantana (*Lantana camara*) (BC Act)
- Invasion of native plant communities by African Olive *Olea europaea* subsp. *cuspidata* (BC Act)
- Invasion of native plant communities by exotic perennial grasses (BC Act)
- Loss and degradation of native plant and animal habitat by invasion of escaped garden plants (EPBC Act/BC Act)
- Novel biota and their impact on biodiversity (EPBC Act)

15.4.7 PREDATION/COMPETITION/LAND DEGRADATION BY PEST/DOMESTIC FAUNA

Development under the Plan has the potential to increase the spread of pest fauna and/or access to natural areas by domestic fauna, leading to increased predation and competition with native fauna. This is primarily related to:

- Clearing that creates new movement pathways that can be used by pest fauna to expand their range
- Clearing that changes conditions at the edges of habitat that favour pest fauna
- Direct predation of native fauna by pest/domestic fauna
- Pest fauna destroying habitat and spreading disease

Domestic animals in this context are primarily related to increased numbers of cats, dogs and rabbits.

Key threatening processes listed under the BC Act and EPBC Act relevant to this indirect impact type are:

- Aggressive exclusion of birds from potential woodland and forest habitat by abundant Noisy Miners *Manorina melanocephala* (EPBC Act/BC Act)
- Competition and land degradation by rabbits (EPBC Act)/Competition and grazing by European rabbit (BC Act)
- Competition and land degradation by unmanaged goats (EPBC Act)/Competition and habitat degradation by Feral Goats, *Capra hircus* (BC Act)
- Competition from feral honeybees (EPBC Act/BC Act)
- Herbivory and environmental degradation caused by feral deer (BC Act)
- Predation and hybridisation by Feral Dogs, *Canis lupus familiaris* (BC Act)
- Predation by feral cats (EPBC Act/BC Act)
- Predation by the European red fox (EPBC Act/BC Act)
- Predation by the plague minnow (*Gambusia holbrooki*) (BC Act)
- Predation, habitat degradation, competition, and disease transmission by feral pigs (*Sus scrofa*) (EPBC Act/BC Act)
- The biological effects, including lethal toxic ingestion, caused by Cane Toads (*Rhinella marina*) (EPBC Act)/Invasion and establishment of the Cane Toad (*Rhinella marina*) (BC Act)

15.4.8 ALTERED FIRE REGIMES AND INCREASED FIRE RISK

Development under the Plan has the potential to alter fire regimes and increase fire risk. This is primarily related to:

- Arson or the accidental lighting of fires
- Increased burns for hazard reduction to protect assets, particularly within Asset Protect Zones
- Reduced burns in some areas due to risk to urban areas

Changed fire regimes can reduce habitat suitability for TECs and threatened species, affect foraging resources, and prey species, and cause direct mortality from heat and smoke.

The key threatening process listed under the BC Act relevant to this indirect impact type is:

- Ecological consequences of high frequency fires (BC Act)

15.4.9 DISTURBANCE FROM INCREASED PUBLIC ACCESS TO NATURAL HABITAT AREAS

Development under the Plan will increase human activity in the vicinity of the nominated areas, which can impact avoided lands, conservation lands secured under the Plan and existing reserves. This is primarily related to:

- Trampling of threatened flora species/habitat for threatened fauna species
- Track creation
- Bush rock removal and disturbance
- Rubbish dumping and disturbance from associated clean-up activities
- Timber collection, removal of dead wood
- Illegal collection of threatened species
- Dog walking
- Recreational activities such as mountain-biking, four-wheel driving, and fishing

Species and TECs most at risk from this threat occur on public land because these areas are publicly accessible.

Key threatening processes listed under the BC Act relevant to this indirect impact type are:

- Bushrock removal (BC Act)
- Removal of dead wood and dead trees (BC Act)

15.4.10 FAUNA MORTALITY AND INJURY, FAUNA DISPLACEMENT AND THE INTRODUCTION OF BARRIERS TO FAUNA MOVEMENT

Development under the Plan may increase the likelihood of fauna mortality and fauna displacement and will introduce barriers to fauna movement. This is primarily related to:

- Direct mortality as a result of collisions with vehicles or new structures, shooting, poaching, or secondary poisoning during pest control
- Displacement due to clearing for the development
- Introduction of linear barriers such as fences, roads, and railways, which can affect fauna movement and predation

Koala, birds, invertebrates, and arboreal mammals are particularly susceptible to these impacts.

15.4.11 FAUNA DISTURBANCE DUE TO NOISE, DUST OR LIGHT

Development under the Plan will increase noise, dust, and light. This is primarily related to:

- Clearing for the development
- Construction activities, including use of heavy vehicles and machinery
- Increased noise levels from traffic due to new roads or increased traffic on existing roads
- Artificial light from urban and commercial areas, and along transport routes

Increased noise can particularly impact on species that vocalise or rely on hearing for hunting or breeding. Artificial light can affect the behaviour of nocturnal and diurnal species, including disorientation, attraction to light sources resulting in collisions and mortality, and effects on light-sensitive life cycles (e.g. flowering, breeding, and migration). Increased light can also influence the abundance, behaviour, and movement of some predator species.

15.4.12 INADVERTENT IMPACTS ON ADJACENT HABITAT OR VEGETATION

Development under the Plan may cause inadvertent impacts on adjacent habitat, vegetation, or important habitat features, such as hollow bearing trees. This could occur during construction or operation and is primarily related to:

- Impacts adjacent to construction sites
- Road, trail, and power line maintenance
- High frequency land management such as mowing and slashing or weed control

This can affect threatened species' habitat which is close to urban capable land and transport corridors.

15.5 SPECIES AND TECS LIKELY TO BE AFFECTED BY INDIRECT IMPACTS

Attachment A identifies the NSW-listed threatened species and TECs potentially impacted by each indirect impact. Indirect impacts were identified as being relevant to a species or TEC if:

- The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, *and*
- The threat is present in the Cumberland subregion, *and/or*
- The Plan has the potential to introduce or exacerbate the threat in a way that may affect the known occurrence of a species, TEC, or associated habitat

Relevant indirect impacts were identified by drawing on distribution, ecological and life history information in BioNet and other species profiles, conservation advices, and recovery plans, and species records and habitat maps prepared for this Assessment Report.

Note that ground settlement and subsidence is only relevant under the Plan to several species and TECs that occur in the vicinity of the transport corridor tunnels. The indirect impacts of the tunnels on these matters are assessed in Chapter 36.

Identification of the potential indirect impacts relevant to Commonwealth-listed TEC and species, as well as other EPBC Act protected matters, are presented in the following detailed assessment chapters:

- Chapter 29 – Commonwealth-listed flora

- Chapter 30 – Commonwealth-listed fauna
- Chapter 31 – Commonwealth-listed TECs
- Chapter 32 – Migratory species
- Chapter 33 – Ramsar wetlands
- Chapter 34 – World and National Heritage
- Chapter 35 – Commonwealth Land

15.6 GENERAL MITIGATION MEASURES AND IMPLEMENTATION PROCESSES

This section:

- Describes the relevant commitments and actions under the Plan to mitigate indirect impacts for each of the different types of development, as well as specifically for Koala
- Describes the processes to implement the mitigation measures for each of the different types of development
- For the urban and industrial development and intensive plant agriculture, identifies a set of 'general mitigation measures' that will be implemented to mitigate indirect impacts

The Plan includes commitments to mitigate the indirect impacts of the urban, industrial, infrastructure, intensive plant agriculture and transport development on biodiversity values and other protected matters. The processes to implement the mitigation measures are different for the types of development under the Plan:

- For the urban and industrial development and intensive plant agriculture, mitigation measures will be implemented through the precinct planning and development application process under the NSW planning system
- For infrastructure development and the major transport corridors, mitigation measures will be implemented through future environmental assessment and approval processes applied at the time of the development

These different implementation processes are described in section 15.6.1, section 15.6.2 and section 15.6.3.

15.6.1 MITIGATION OF URBAN AND INDUSTRIAL DEVELOPMENT AND INTENSIVE PLANT AGRICULTURE

COMMITMENTS AND ACTIONS

The Plan includes a commitment to mitigate indirect and prescribed impacts from urban and industrial development and intensive plant agriculture on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan (Commitment 5).

Note Commitment 5 also applies to infrastructure, but the commitment is implemented differently for this type of development, and this is discussed in section 15.6.2.

The key actions under Commitment 5 to implement the mitigation measures for urban and industrial development and intensive plant agriculture are set out in Table 15-2.

Table 15-2: Actions to mitigate indirect impacts for urban and industrial development and intensive plant agriculture

Implementation mechanism or process	Actions under Commitment 5 to mitigate indirect impacts
Development Control Plans (DCPs), implemented through development application process under EP&A Act	1. Incorporate development controls in the State-led DCPs for each nominated area setting out development controls that need to be addressed by neighbourhood plans and development applications to mitigate indirect and prescribed impacts on threatened species. This includes: a. Specific controls that apply to the nominated areas to mitigate indirect and prescribed impacts on specific threatened species or ecological communities or other environmentally sensitive areas in accordance with Appendix E of the Plan

Implementation mechanism or process	Actions under Commitment 5 to mitigate indirect impacts
	b. A common set of development controls to mitigate indirect and prescribed impacts across the four nominated areas that inform general biodiversity protection as listed in Chapter 15 of the Assessment Report [see Table 15-4 to Table 15-13] 2. Work with local councils to incorporate development controls in relevant council-based DCPs for the nominated areas 3. Provide ongoing support to local councils in the application of DCP controls within the nominated areas, including the sharing of knowledge, maps and data 4. Audit DCPs to ensure the Cumberland Plain Conservation Plan DCP Template development controls are incorporated in accordance with the DCP requirements for each nominated area 5. Monitor the implementation of development controls through approval conditions by the relevant consent authority. If monitoring finds that controls are not being implemented, review and redraft new controls to update relevant State DCPs and re-educate councils to ensure stronger consideration of the controls through their assessment process

IMPLEMENTATION PROCESS FOR MITIGATION MEASURES

The key mechanism to implement mitigation measures to address the indirect impacts of the urban and industrial development and intensive plant agriculture on biodiversity values is Development Control Plans (DCPs).

DCPs will be prepared for each nominated area and will set out development controls to address indirect impacts. The development controls in DCPs will be implemented through the standard development application process under the EP&A Act that occurs prior to urban and industrial development and intensive plant agriculture proceeding.

DCPs will incorporate the following types of development controls:

- Development controls identified in the Plan and this Assessment Report, including:
  - Common set of controls that apply across the nominated areas that inform general biodiversity protection. These controls are commonly implemented by planning authorities to manage indirect impacts through the development application process. These are identified in Table 15-4 to Table 15-13
  - Specific controls that apply to specific species and TECs in certain locations. These controls have been identified through this Assessment Report and are needed to address the residual risks that remain after the common set of controls are applied. These are identified in Appendix E of the Plan and section 15.8 of this Assessment Report
- A broader set of development controls that address indirect impacts on environmental values generally. These controls are commonly implemented by planning authorities through the development application process to manage indirect impacts on environmental values generally, such as impacts relating to hydrology and water quality, soil erosion, contaminated land, air quality, noise, and traffic

Development Control Plans

What is the legal framework for DCPs?

DCPs are non-legally binding planning policies that provide detailed planning and design guidelines, including development controls. DCPs are made under Division 3.6 of the EP&A Act.

Section 3.46 of the EPA Act provides that the purpose of a DCP is to:

- Give effect to the aims of any environmental planning instrument that applies to the development
- Facilitate development that is permissible under any such instrument
- Achieving the objectives of land zones under any such instrument

A DCP provides detailed guidelines and environmental standards for new development. DCPs are used by councils in the assessment of development applications. When designing development proposals, applicants need to address the relevant requirements of any DCPs which apply to their land or proposal.

Any development assessed under Part 4 of the EP&A Act must consider the relevant DCP.

Who prepares the DCP?

A DCP will be prepared for each nominated area. DCPs will be prepared either by the Department (in the case of Department led precincts) or by the relevant councils in collaboration with the Department.

Council will lead the preparation of DCPs for GMAC and GPEC.

What is the process for preparing the DCP?

DCPs will be prepared in accordance with:

- A DCP template prepared by the Department to support implementation of the Plan – this is described below (see under section 'Implementation of mitigation measures for biodiversity values identified in the Plan')
- Standard format for DCPs and a set of model provisions that apply across NSW
- Any processes and guidelines for preparing DCPs specific to each Council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

Draft DCPs must be exhibited for public consultation, whether prepared by the council or the Department. This provides an opportunity for stakeholders to raise issues and improve the DCP.

DCPs will be reviewed in five-year intervals and updated if necessary. This process allows new development controls to be incorporated into the DCP or controls to be amended to ensure they meet best practice standards.

How will the controls in the DCP be implemented?

Councils will be responsible for imposing conditions on developers requiring the implementation of development controls under the DCP through the development application process.

The Department will work with councils to ensure appropriate conditions are incorporated within each subdivision plan and development approval to support the implementation of the mitigation measures.

What assurance measures are in place to ensure mitigation measures are implemented and risks of failure addressed?

The Plan puts in place several assurance measures to ensure implementation of mitigation measures occurs consistent with the Plan and to address any uncertainty or risks of failure. These measures include:

- Monitoring the implementation of the development controls through approval conditions by councils. If monitoring finds that development controls are not being implemented, the Department will review and redraft new controls to update relevant State DCPs or re-educate councils to ensure stronger consideration of the controls through the development application process (see Commitment 5, Action 4)
- Implementing an evaluation program (Commitment 25) that will monitor and report and evaluate the delivery of commitments and actions. This provides a process to ensure the commitment to mitigate indirect and prescribed impacts (Commitment 5) is achieved and actions and processes are adjusted, if necessary, through adaptive management processes (see Chapter 9 and Chapter 16)

Who will ensure compliance?

The NSW planning system provides an existing compliance framework under which planning authorities can take action under the EP&A Act to ensure compliance with the Plan's requirements for addressing indirect impacts. This allows planning authorities to enforce development controls in the DCP template that are incorporated as conditions of consent by planning authorities through the development application process.

The Plan also commits to implementing a compliance program (Commitment 26) to ensure compliance with the requirements of the Plan and conditions of approval (see Chapter 9). As part of this, a compliance strategy will be

prepared. This provides a process to ensure procedures and roles and responsibilities for compliance action in relation to implementation of development controls is clear and co-ordinated across planning authorities.

The Plan will also fund six full-time compliance officers to work with local councils to carry out compliance activities in the Plan Area, and includes additional actions to:

- Share knowledge, maps and data and provide ongoing support and training to council staff to assist councils with carrying out implementation and compliance activities
- Publish a compliance report as part of the yearly update on implementation of the Plan and provide to local councils for review and investigation
- Prepare reports at least every two years on any identified breaches with Plan commitments and approval conditions, such as auditing development consent conditions

Implementation of mitigation measures for biodiversity values identified in the Plan

The assessment of the indirect impacts led to the identification of a common set of development controls (identified in Table 15-4 to Table 15-13) and a specific set of development controls (identified in Appendix E of the Plan and section 15.8 to address residual impacts) that are needed to address indirect impacts on biodiversity values.

DCP template

The Department has prepared a DCP template that provides model provisions to help ensure the mitigation measures identified in the Plan are incorporated into DCPs and applied consistently across the nominated areas.

The DCP template includes both the:

- Common set of controls identified in Table 15-4 to Table 15-13
- Specific controls identified in Appendix E of the Plan and section 15.8

The Department will incorporate the development controls in the DCP template into Department led DCPs. For GMAC and GPEC that do not have a Department-led DCP in place, the Department has prepared the *Cumberland Plain Conservation Plan Mitigation Measures Guidelines* (Mitigation Measures Guidelines). The Mitigation Measures Guidelines apply the same mitigation measures that would otherwise be implemented through Department-led DCPs in accordance with Appendix E of the Plan. The guidelines do not include the common set of controls included in the DCP template.

Implementation of the development controls in the DCP template and Mitigation Measures Guidelines requires planning authorities to make decisions around the circumstances, design specifics and exact locations where the controls should be applied. This is appropriate due to the scale of the development under the Plan and the long timeframe over which it will be implemented.

The Department will support councils to make these decisions (see Commitment 5, Action 3) through providing information in the Assessment Report on the risks of indirect impacts to specific species and TECs and locations, data on biodiversity values collected as part of this Assessment Report, guidance on best practice standards, and specific advice related to Koala mitigation through the Koala working group (see section 15.6.4).

The Department will also audit the DCP prepared by councils to ensure the controls in the DCP template and Mitigation Measures Guidelines are incorporated in accordance with the Plan's requirements (see Commitment 5, Action 5).

Implementation of mitigation measures for broader environmental values

Planning authorities typically incorporate a range of controls in DCPs that are broader in scope to those identified in Table 15-4 to Table 15-13 to manage the indirect impacts of development on broader environmental values, such as impacts relating to hydrology and water quality, soil erosion, contaminated land, air quality, noise and traffic.

Examples of these types of controls included in the draft Wilton DCP are provided in Table 15-3.

These controls are not identified in the DCP template as it is standard practice to incorporate these sorts of controls into DCPs across NSW to manage the impacts of development on the environment.

Councils will be responsible for making decisions about the specifics of these controls in each DCP and through the development application process based on best practice standards and guidelines.

This Assessment Report assumes these types of controls will be incorporated into each DCP for each nominated area where planning authorities consider these necessary. These controls will be important to manage the indirect impacts of the urban and industrial development and intensive plant agriculture on biodiversity values within the nominated areas and downstream and outside of the nominated areas, including the Towra Point Ramsar wetland and Commonwealth land. These controls are discussed further in Chapter 33 (Ramsar wetlands) and Chapter 35 (Commonwealth land).

Table 15-3: Summary examples of broader environmental controls commonly included in DCPs (from draft Wilton DCP)

Control type	Summary of example control in draft Wilton DCP
Water cycle management	• Water management measures must comply with council's requirements for detention, drainage, and water sensitive urban design principles • Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise run-off and sediment and pollutants to waterways
Water quality	• Stormwater systems must be constructed/maintained to achieve EES water quality targets
Soil erosion and sedimentation	• Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development • Soil and Water Management Plans must be prepared in accordance with *Managing Urban Stormwater* (Landcom, 2004) and included in development applications
Disturbance to saline soils	• Salinity Management Plans must be prepared in accordance with the *Western Sydney Salinity Code of Practice 2004* (WSROC, 2004) and included in development applications
Contaminated land	• Development is to be in accordance with the *Contaminated Land Management Act 1997* and *State Environmental Planning Policy 55 – Remediation of Land* • Development applications must be accompanied by a Stage 1 Preliminary Site Investigation. Where this identifies potential site contamination, a Stage 2 detailed site investigation must be prepared • A Remediation Action Plan (RAP) must be prepared for areas identified as contaminated land in the Stage 2 Site Investigation
Air quality	• Development must comply with the *Protection of the Environment Operations Act 1997* and supporting regulations. An Odour Impact Assessment must be submitted when required • Provide a barrier to mitigate dispersion of air pollutants, noise, or odour where necessary
Noise	• Provide a barrier to mitigate dispersion of air pollutants, noise, or odour • Development must include buffers to limit noise impacts on surrounding areas • An acoustic report must be submitted to address the impact of noise generation
Traffic/construction traffic	• Ensure the road networks are designed to control traffic speeds to appropriate limits • Provide a traffic report/statement to address the impact of the development on the local road system and address traffic safety issues

GENERAL MITIGATION MEASURES

General environmental controls that are commonly implemented by planning authorities in NSW through the development application process and are included in the DCP template are summarised in:

- Table 15-4 for mitigation of construction impacts
- Table 15-5 for protection of waterways and riparian corridors
- Table 15-6 for mitigation of the spread of disease/infection
- Table 15-7 for mitigation of spread of weeds
- Table 15-8 for mitigation of pest/domestic fauna impacts
- Table 15-9 for mitigation of altered fire regimes
- Table 15-10 for mitigation of fauna mortality, fauna displacement and impacts from linear barriers
- Table 15-11 for mitigation of fauna disturbance due to noise, dust, and light
- Table 15-12 for mitigation of inadvertent impacts on adjacent habitat or vegetation

- Table 15-13 for retention of key habitat features

The tables summarise the general environmental controls and identify any relevant standards, targets or guidelines that apply to the design or implementation of the controls.

The specific controls that apply to specific species and TECs in certain locations in the nominated areas, which are identified in Appendix E of the Plan, are described in section 15.8.

Construction impacts

Table 15-4: Development controls specific to mitigation of indirect impacts from construction

Summary of key controls	Relevant standards, targets, or guidelines

• Prepare a Construction Environmental Management Plan (CEMP) setting out measures to protect the environment during construction, including:
  ○ Pre-clearance assessment for native fauna prior to any clearing native vegetation
  ○ Best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust
  ○ Site rehabilitation and installation of nest boxes for development adjacent to natural areas
  ○ Tree felling protocol to avoid impacts to species relying on tree hollows, dreys, dens, and other nests in trees that are to be cleared
• Submit a weed eradication and management plan with development applications for subdivision outlining weed control measures during and after construction
• Construction traffic to utilise clearly defined access and egress points to and from a development site to avoid remnant wildlife corridors and native vegetation communities
• Parking and equipment and laydown areas to be located away from land with biodiversity values
• Temporary fencing to be erected to manage inadvertent impacts on adjacent natural areas
	Relevant council specifications
	Arrive Clean, Leave Clean: Guidelines (Commonwealth of Australia, 2015)

Waterways and riparian corridors

Table 15-5: Development controls to manage waterways and riparian corridors

Summary of key controls	Relevant standards, targets, or guidelines
• Maintain waterways of Strahler order 2 or higher in a natural state, including the maintenance and restoration of riparian corridors • Where development will affect a waterway of Strahler order 2 or higher, rehabilitate the waterway to return it to a natural state • Design road crossings of waterways to minimise impacts to vegetated riparian corridors and species movements Note under the EPA Act, development within 40 m of a watercourse is Integrated Development and requires approval under the *Water Management Act 2000*	• Relevant councils design and construction specifications • Strahler ordering scheme for waterways

Spread of infection/disease

Table 15-6: Development controls to manage the spread of infection/disease

Summary of key controls	Relevant standards, targets, or guidelines
• Prepare a Construction Environmental Management Plan (CEMP) setting out the measures and methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust	Arrive Clean, Leave Clean: Guidelines (Commonwealth of Australia, 2015)

Spread of weeds

Table 15-7: Development controls to manage the spread of weeds

Summary of key controls	Relevant standards, targets, or guidelines
• Submit a weed eradication and management plan with development applications for subdivision outlining weed control measures during and after construction • Subdivision design and bulk earthworks to minimise environmental weed spread and include measures to eradicate these weeds in accordance with relevant council weed policies • Weeds of National Significance and on the National Environmental Alert List under the National Weeds Strategy to be managed and eradicated. Proponent to reference NSW Weed Wise for current weed identification and management approaches	Relevant council weed policies National Weeds Strategy NSW Weed Wise Plan's weed control strategy

Predation/competition/land degradation by pest/domestic fauna

Table 15-8: Development controls to manage the impacts from pest/domestic fauna

Summary of key controls	Relevant standards, targets, or guidelines
Domestic animals • Ensure that domestic animals are appropriately contained at urban/bushland interfaces • Property boundaries should have appropriate fencing to contain domestic animals within the landholders' property	
Pest animals • Appropriately manage and control pest animals as relevant to the site • Pest control techniques implemented during and post construction to be in accordance with regulatory requirements for chemical use	Plan's pest animal control strategy

Altered fire regimes and increased fire risk

Table 15-9: Development controls to manage impacts from altered fire regimes and increased fire risk

Summary of key controls	Relevant standards, targets, or guidelines
• APZs for bushfire protection purposes are to be located wholly within the urban capable land for new development and not within land with biodiversity values As part of commitment 2, the Plan includes an action that specifies APZs are to be located wholly within urban capable land (see section 'Asset Protection Zones' below). The appropriate APZ distance is determined by the Rural Fire Service Standards for Asset Protection based on vegetation type, slope and the nature of the development and is measured from the edge of the retained habitat	RFS Standards for Asset Protection

Fauna mortality and injury, fauna displacement and the introduction of linear barriers

Table 15-10: Development controls to manage fauna mortality, fauna displacement and impacts from the introduction of linear barriers

Summary of key controls	Relevant standards, targets, or guidelines
• Implement traffic calming measures in development areas not subject to koala exclusion fencing, including speed limit restrictions for areas adjacent to land with biodiversity values, and installation of wildlife signposting and speed humps and audible surfacing in accordance with relevant standards • Install and maintain fauna-friendly road design structures in appropriate areas adjacent to fauna habitat, such as underpasses, fauna bridges and overpasses	TfNSW Biodiversity Guidelines Relevant council guidelines Relevant Australian Standards

Fauna disturbance due to noise or light

Table 15-11: Development controls to manage fauna disturbance due to noise and light

Summary of key controls	Relevant standards, targets, or guidelines
• Where noise or light impacts from development on land adjacent to natural areas may affect wildlife, mitigation measures to manage impacts should be implemented, such as managing the timing of activities and/or installing appropriate noise barriers • High-intensity outdoor lighting, including commercial lighting, or sports fields lighting, should be designed to avoid light spill into adjoining natural areas • Development within 100 m of known microbat colonies or habitat likely to support microbat colonies must include street lighting that does not attract insects	Australian Standard AS 4282 Commonwealth's *Draft Light Pollution Guidelines for Wildlife*

Inadvertent impacts on adjacent habitat or vegetation

Table 15-12: Development controls to manage inadvertent impacts on adjacent habitat or vegetation

Summary of key controls	Relevant standards, targets, or guidelines
• Parking and equipment and laydown areas to be located away from land with biodiversity values • Temporary fencing to be erected to manage inadvertent impacts on adjacent natural areas	

Retention of key habitat features or important sites

Table 15-13: Development controls to retain key habitat features

Summary of key controls	Relevant standards, targets, or guidelines

• Establish ecological setbacks in accordance with distances in the DCP to provide a buffer to adjacent development for:
  ○ Raptor nests
  ○ Grey-headed Flying Fox camps	

The role of asset protection zones in buffering indirect impacts

An asset protection zone (APZ) is a buffer zone between a bushfire hazard and buildings or other infrastructure that needs to be protected. It is managed to minimise fuel loads and reduce potential radiant heat levels, flames, localised smoke, and ember attack. The width of the APZ is generally between a minimum of 20 m and 60 m. This is determined based on vegetation type, slope, and the nature of the development, in accordance with Rural Fire Service standards. As part of the subdivision design, the APZ may include perimeter roads or open space areas.

Commitment 2 of the Plan includes an action that specifies APZs are to be located wholly within urban capable land when preparing new precinct plans for nominated areas.

This commitment is given legal effect in the Strategic Conservation Planning SEPP (see Chapter 9). Clause 12 of the SEPP specifies that development consent must not be granted on urban capable land unless any asset protection zone is located wholly within the urban capable land.

APZs will act as a buffer between the urban and industrial development and intensive plant agriculture and adjacent biodiversity values, including avoided lands and other areas containing TECs and species habitat. This buffer will reduce the risk, and support the mitigation of, several indirect impacts, including in relation to:

- Waterways and riparian corridors
- Water quality
- Weed invasion
- Altered fire regimes
- Inadvertent impacts on adjacent habitat or vegetation

OTHER REGULATION RELATING TO INTENSIVE PLANT AGRICULTURE

Intensive plant agriculture is regulated by other legislation in addition to the EP&A Act that is relevant to managing potential indirect impacts associated with the use of water resources and chemicals and pesticides. This additional legislation includes the *Water Management Act 2000* (WM Act) and the *Pesticides Act 1999*.

Under the WM Act, proponents of intensive plant agriculture seeking to use surface or groundwater will be required to obtain a licence from Water NSW. The licence will be granted in accordance with the relevant Water Sharing Plan (*Water Sharing Plan for the Greater Metropolitan Region Unregulated River Water Sources 2011*). The licence process ensures water extraction occurs within sustainable limits set under the plan. Water Sharing Plans are reviewed and updated every 10 years to ensure the rules, including extraction limits, continue to meet the objectives of each plan.

The regulation of pesticides in NSW is part of a national scheme co-ordinated under Commonwealth legislation that provides a framework for approval, registration, labelling and management of pesticides in Australia. The framework has been adopted in NSW under the *Agricultural and Veterinary Chemicals (New South Wales) Act 1999*.

The use of pesticides in NSW is further regulated by the *Pesticides Act 1999*. Under this Act, a proponent of intensive plant agriculture may need a permit to use pesticides, and the Act includes a range of offences for using pesticides in contravention of any instruction or label, causing harm to any non-target animals or plants, including specific provisions for threatened species, and for negligent misuse of pesticides. The NSW Environment Protection Authority can make pesticide control orders to prohibit or control the use of a pesticide and protect the environment, as well as issue prevention notices or clean up notices. The Act also establishes a specific licensing regime for aerial spraying. Only a person with the necessary qualifications can obtain an aerial spraying licence.

Intensive plant agriculture will need to meet the requirements of the WM Act and *Pesticides Act* 1999 in addition to being regulated under the EP&A Act. It is expected these existing legislative frameworks will adequately address potential indirect impacts from intensive plant agriculture in relation to the use of water resources and chemicals and pesticides.

15.6.2 MITIGATION MEASURES FOR INFRASTRUCTURE

COMMITMENTS AND ACTIONS

The Plan includes a commitment to mitigate indirect impacts from infrastructure on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan (Commitment 5).

The key actions under Commitment 5 to implement the mitigation measures for infrastructure are set out in Table 15-14.

Note Commitment 5 also applies to urban and industrial development and intensive plant agriculture, but the commitment is implemented differently for these types of development, and this is discussed in section 15.6.1.

Table 15-14: Actions to mitigate indirect impacts for infrastructure development

Implementation mechanism or process	Actions under Commitment 5 to mitigate indirect impacts
Cumberland Plain Conservation Plan Guidelines for Infrastructure Development, implemented through future environmental assessment and approval processes under EP&A Act	1. Introduce Cumberland Plain Conservation Plan Guidelines for Infrastructure Development to be addressed by a public authority that includes mitigation measures for indirect and prescribed impacts to biodiversity from infrastructure activities in accordance with Appendix E of the Plan 2. Identify and implement mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the requirements of the NSW approval processes under the EP&A Act, as well as published, best practice guidelines

IMPLEMENTATION PROCESS FOR MITIGATION MEASURES

The key mechanism to implement mitigation measures to address the indirect impacts of infrastructure is the *Cumberland Plain Conservation Plan Guidelines for Infrastructure Development* (infrastructure guideline).

The infrastructure development guideline will set out development controls to address indirect impacts. The development controls in the guideline will be implemented through future environmental assessment and approval processes under the EP&A Act that will apply to each infrastructure project prior to it proceeding.

The infrastructure development guideline is supported by the SEPP (Strategic Conservation Planning). The SEPP requires local development under Part 4 of the EP&A Act to take the guideline into consideration. The SEPP and the EP&A Regulation 2000 also specify notification requirements.

Note that infrastructure under the Plan will generally be limited to urban capable land within the nominated areas. Infrastructure that meets the definition of 'essential infrastructure' (see Part 2) may be carried out on avoided land without further approval under the EPBC Act if certain requirements are met. The direct and indirect impacts of essential infrastructure and commitments to address these impacts are assessed in Chapter 37.

Future environmental assessment processes

Infrastructure will be subject to future environmental assessment and approval processes under the EP&A Act at the time the projects are proposed. Infrastructure covering the broad types under the Plan (see Part 2) is subject to different environmental assessment processes. These are summarised in Table 15-15.

SEPP (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed and approved under the EP&A Act. The SEPP sets out:

- What type of infrastructure is approved by council, the Minister for Planning, or Department under a traditional development consent process under Part 4 of the EP&A Act (this is known as 'development with consent')
- What type of infrastructure development is approved by a public authority under a separate process under Part 5 of EP&A Act (this is known as 'development without consent')
- What type of development is exempt from requiring approval (known as 'except development') or may be undertaken provided certain conditions are met (known as 'complying development')

Table 15-15: Potential assessment and approval processes for infrastructure under the Plan

	Approval	Assessment	Assessment mechanism	Approval body
Part 4	Approval required under Part 4 of EP&A Act	Must include an assessment of the 'likely impacts of the development, including environmental impacts on both the natural and built environments and social and economic impacts…' (s 79C(1))	Environmental Impact Statement (for State Significant Development) Statement of Environmental Effects (for other development)	Normally council For State Significant Development, may be: • Minister for Planning • Planning Assessment Commission • The Department
Part 5	Approval required under Part 5 of EP&A Act	Must 'examine and take into account to the fullest extent possible all matters affecting or likely to affect the environment by reason of that activity' (s 111)	Review of Environmental Factors Environmental Impact Statement	Normally a public authority
SSI	Approval required under Part 5.1 of EP&A Act	Must prepare an Environmental Impact Statement in accordance with assessment requirements specified by the Department	Environmental Impact Statement	Minister for Planning

Implementation of mitigation measures for biodiversity values identified in the Plan

The assessment of the indirect impacts of infrastructure in section 15.7 led to the identification of several mitigation measures that apply to specific species and TECs in certain locations in the nominated areas to address the indirect impacts of infrastructure on biodiversity values.

These mitigation measures are identified in Appendix E of the Plan and section 15.8 of this Assessment Report.

The Department will prepare a guideline under clause 228 of the EP&A Regulation – the *Cumberland Plain Conservation Plan Guidelines for Infrastructure Development* (infrastructure guideline).

The objectives of the infrastructure guideline are to:

- Ensure infrastructure provision is consistent with biodiversity conservation approvals under the Plan
- Mitigate impacts of infrastructure on certified—urban capable land

The infrastructure guideline must be taken into account when public authorities consider the likely impact of infrastructure on the environment under the EP&A Act. The guideline supports implementation of the Plan by ensuring the mitigation measures in the Plan are considered and implemented through the future environmental assessment and approval processes under the EP&A Act that will be undertaken for each infrastructure project.

Part 3.3 of the infrastructure guidelines apply to infrastructure proposed under Part 5 of the EP&A Act on urban capable land. It identifies mitigation requirements that must be addressed to ensure consistency with the Plan's requirements for mitigating the indirect impacts of infrastructure projects. The guideline includes:

- Objectives that align with the commitments in the Plan, including Commitment 5, to address indirect impacts

- A set of mitigation measures relevant to addressing the indirect impacts of infrastructure. These measures have been identified through this Assessment Report (see section 15.8) and are reflected in Appendix E of the Plan

Implementation of mitigation measures for broader environmental values

Public authorities typically incorporate a broader set of mitigation measures to those identified in Appendix E of the Plan to manage the indirect impacts of infrastructure development on the environment generally, including impacts relating to hydrology and water quality, soil erosion, contaminated land, air quality, noise, and traffic.

As required under Commitment 5, Action 2, the future environmental assessment and approval processes under the EP&A Act undertaken by public authorities for each infrastructure project will lead to the identification and implementation of these broader mitigation measures based on the detailed design of each project.

These broader mitigation measures are not identified in Appendix E of the Plan and section 15.8 as it is a requirement of the assessment processes under the EP&A Act to identify and implement these sorts of measures and incorporate them into approval conditions for infrastructure projects. Commitment 2, Action 2 provides additional assurance that this process will occur as part of this future assessment process for each infrastructure project.

Public authorities will be responsible for making decisions about the specifics of these mitigation measures for each project through the future environmental assessment processes based on best practice standards and guidelines.

15.6.3 MITIGATION MEASURES FOR THE TRANSPORT CORRIDORS

COMMITMENTS AND ACTIONS

The Plan includes a commitment to mitigate indirect impacts on TECs, species and their habitat within major transport corridors, including the Outer Sydney Orbital and Metro Rail Future Extension tunnel sections (Commitment 6), in accordance with the:

- Major transport corridors class of action description, including the NSW State Significant Infrastructure (SSI) (or equivalent) approval for certified-major transport corridors
- Major infrastructure corridors class of action description and the BC Act (or equivalent) for non-certified major transport corridors (strategically assessed)
- Specific mitigation measures to address impacts on biodiversity values prescribed in Appendix E

The key actions under Commitment 6 to implement the mitigation measures for infrastructure are set out in Table 15-16.

Table 15-16: Actions taken under the Plan to mitigate indirect impacts from the transport corridors

Implementation mechanism or process	Actions under Commitment 6 to address indirect impacts
Actions under Commitment 6, implemented through or alongside future environmental assessment processes for each transport project under EP&A Act and/or BC Act	Transport for NSW will, across all major transport corridors: 1. Assess the impacts on biodiversity values listed under the BC Act (for non-certified major transport corridors) and other environmental values (for certified- and non-certified major transport corridors) based on detailed design 2. Implement specific mitigation measures prescribed in Appendix E and identify and implement additional mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the SSI (or equivalent) approval process, as well as best practice guidelines, including the RMS Biodiversity Guidelines 3. Apply further mitigation according to the BC Act and BAM (or equivalent) for non-certified major transport corridors (strategically assessed), including the tunnels 4. Offset impacts to biodiversity values, including MNES, in accordance with the BAM (or equivalent) and *EPBC Act Environmental Offsets Policy* should there be long-term detrimental impacts from subsidence due to the tunnel sections 5. Identify potential design options for major watercourse crossings to reduce disruption to connectivity and the risk of vehicle strikes 6. Establish baseline monitoring data and undertake ongoing monitoring of high-value environmental areas, and review and adjust mitigation measures (where practical) in response to monitoring outcomes, in accordance with the SSI (or equivalent) approval 7. Report to the Department and executive implementation committee on mitigation measures proposed to manage impacts of each transport project, including proposed techniques, timing, frequency and responsibility for implementing each measure and any offsets to be secured in accordance with the BAM (or equivalent) and *EPBC Act Environmental Offsets Policy* due to subsidence impacts of the tunnels

IMPLEMENTATION PROCESS FOR MITIGATION MEASURES

The key processes to implement mitigation measures to address the indirect impacts of the major transport corridors is a series of actions that Transport for NSW is required to implement under Commitment 6.

These actions will be implemented through or alongside future environmental assessment and approval processes under the EP&A Act and/or the BC Act that will apply to each transport project prior to it proceeding. The assessment process will depend on whether the transport project is proposed for certification under the Plan:

- For the certified major transport corridors, the environmental assessment process will comprise the SSI (or equivalent) assessment process under the EP&A Act
- For the non-certified major transport corridors (strategically assessed), the environmental assessment process will comprise both the SSI (or equivalent) and the BC Act and BAM (or equivalent) assessment processes

The actions under Commitment 6 ensure Transport for NSW identifies and implements mitigation measures to address indirect impacts based on the detailed design of each transport project (Action 1) through or alongside the future environmental assessment and approval processes under the EP&A Act and/or the BC Act.

For the certified major transport corridors (where indirect impacts on biodiversity values are assessed in this Assessment Report), this involves identifying and implementing mitigation measures to address indirect impacts on broader environmental values based on the outcomes of the SSI (or equivalent) assessment process.

For the non-certified major transport corridors (strategically assessed) (where indirect impacts on biodiversity values are only assessed under the EPBC Act in this Assessment Report), further mitigation measures are required to be identified and implemented based on the outcomes of the assessment and approval under the BC Act and BAM.

Action 2 requires the specific mitigation measures in Appendix E under the Plan to be implemented alongside the future assessment processes for both the certified and non-certified major transport corridors.

Transport for NSW is also required to offset impacts to biodiversity values, including MNES, in accordance with the BAM and EPBC Act Environmental Offsets Policy should there be long-term detrimental impacts from subsidence due to the tunnel sections. The indirect impacts of the tunnel sections are assessed in Chapter 36

Commitment 6 also includes several actions that provide additional assurance in relation to the implementation of the mitigation measures in Appendix E of the Plan and the SSI assessment process. These are:

- Monitoring of high environmental value areas and adjusting of mitigation measures where practical in accordance with the requirements of the SSI (or equivalent) assessment process (Action 6)
- Reporting to the Department and executive implementation committee on the implementation of the mitigation measures for each transport project (Action 7)

These actions provide additional assurance that the SSI and BAM assessment processes will lead to the implementation of mitigation measures to address indirect impacts of the major transport corridors in accordance with Commitment 7.

SSI assessment and approval process

How does the process work?

The EP&A Act provides the primary legislative basis for assessing and approving the impacts of transport development on the environment. The EP&A Act includes provisions to ensure that all potential environmental impacts of a development, including indirect impacts, are assessed and considered in the decision-making process.

Major road and rail projects, including the major transport corridors, are dealt with under the SSI provisions (Division 5.2 of the EP&A Act) and require approval of the Minister for Planning. Under this Division, proponents must:

- Prepare an Environmental Impact Statement (EIS) for the project that assesses the impacts of the development
- Prepare the EIS in accordance with the Planning Secretary's environmental assessment requirements

The Department has prepared a standard set of environmental assessment requirements for SSI projects (DPIE, 2020b). The SEARs reflect the Department's preferred approach to conditioning projects through the provision of performance or outcome focused conditions, and currently requires the assessment to:

- Assess and identify impacts, including indirect impacts
- Propose measures to mitigate impacts
- Nominate and commit to performance outcomes for managing impacts
- Identify the detail of proposed management plans and monitoring programs

Will all relevant indirect impacts be mitigated?

The SSI process requires the EIS to identify all relevant indirect impacts, propose measures to mitigate impacts, commit to performance outcomes, and identify proposed management plans and monitoring programs (DPIE, 2020b).

The Department has prepared indicative standard conditions for linear SSI projects (DPIE, 2020b). These conditions include requirements to prepare construction and operational environmental management plans to set out how performance outcomes, commitments and mitigation measures identified in the EIS, including in relation to managing indirect impacts, will be implemented and achieved. These plans must include:

- A program for ongoing analysis of the key environmental risks associated with the development
- Details of how the development will be undertaken to meet the performance outcomes identified in the environmental impact assessment and manage the risks identified in the risk analysis
- A protocol for managing and reporting any non-compliances with the approval

Are mitigation standards best practice and can they be adapted over time?

The Department's preferred approach to conditioning major projects such as transport development is through performance or outcome focused conditions where appropriate. Under this approach, performance outcomes are identified that must be complied with to achieve an appropriate environmental outcome, but how those outcomes are best achieved through mitigation measures is flexible. An advantage of this approach is that it allows flexibility over time about what mitigation measures are implemented to best achieve the outcome.

The Department has prepared guidelines for identifying mitigation measures to manage impacts in environmental impact assessments, including guidance on implementing performance-based approaches to mitigation (DPE, 2017).

What measures are in place to address any risk of failure of mitigation measures?

The indicative standard conditions for linear SSI projects (DPIE, 2020b) include requirements to prepare construction and operational monitoring programs to monitor performance outcomes, commitments and mitigation measures identified in the EIS. The purpose of the programs is to compare actual performance against predicted performance in the EIS so that adjustments to performance outcomes, commitments and mitigation measures can be made if necessary.

The monitoring programs must provide details of:

- Baseline data to be obtained
- Parameters of the project to be monitored
- Frequency and location of monitoring
- Reporting on monitoring results
- Procedures to identify and implement additional mitigation measures where necessary

Who will ensure compliance?

The indicative standard conditions for linear SSI projects (DPIE, 2020b) provide a detailed set of conditions for each SSI project. Any breach of these conditions is a breach of the approval and is enforceable under EP&A Act.

The set of conditions require the preparation of compliance reports that report on the monitoring and compliance program and the compliance status of a project in relation to compliance with the conditions of approval. Compliance reports must be prepared in accordance with detailed guidelines on compliance reporting (DPE, 2018a). The Department will review the compliance report and respond to any non-compliances in accordance with powers under the EP&A Act and processes outlined in the Department's Compliance Policy (DPE, 2018b).

Implementation of mitigation measures for biodiversity values identified in the Plan

The assessment of the indirect impacts of the major transport corridors in section 15.7 led to the identification of several mitigation measures that apply to specific species and TECs in certain locations in the nominated areas to address the indirect impacts of the transport corridors on biodiversity values.

These mitigation measures are identified in Appendix E of the Plan and section 15.8 of this Assessment Report.

Commitment 6, Action 2 requires Transport for NSW to implement the mitigation measures in Appendix E for the certified major transport corridors and non-certified major transport corridors (strategically assessed).

Implementation of mitigation measures for broader environmental values

Proponents typically incorporate a range of other mitigation measures that are broader in scope to those identified in Appendix E of the Plan to manage the indirect impacts of transport development on broader environmental values including impacts relating to hydrology and water quality, soil erosion, contaminated land, air quality, noise and traffic.

As required under Commitment 6, Action 2, the future SSI assessment and approval process undertaken by Transport for NSW for each transport project will lead to the identification and implementation of these broader environmental mitigation measures based on the detailed design of each transport project.

These broader environmental mitigation measures are not identified in Appendix E of the Plan as it is a requirement of the future SSI assessment process to identify and implement these sorts of measures. Commitment 6, Action 2 provides additional assurance that this process will occur as part of the future assessment process for each transport project.

Proponents and regulators will be responsible for making decisions about the specifics of these broader measures for each project through the future SSI assessment process based on best practice standards and guidelines.

15.6.4 MITIGATION MEASURES FOR KOALA

The Plan includes a range of commitments and actions to protect Koalas from indirect impacts. These include:

- Commitment 2.2 to prioritise the avoidance of impacts from essential infrastructure on non-certified land to important Koala corridors within Wilton and GMAC
- Commitment 7 to mitigate indirect and prescribed impacts from urban, industrial and infrastructure development on the Southern Sydney population to best practice standards and in line with advice from the NSW Chief Scientist, and in accordance with Appendix E of the Plan. This includes actions to:
    - Install exclusion fencing between Koala habitat and urban capable land in GMAC and Wilton to separate Koalas from urban threats, or in areas where exclusion fencing is not feasible, implement additional development controls to minimise impacts to Koalas
    - Install exclusion fencing on both sides of Appin Road to mitigate risk of road mortality
    - Establish a Koala working group to support implementation of Koala commitments and actions
    - Work with relevant stakeholders to manage the threats posed by dogs
    - Provide safe fauna crossings in a range of locations to ensure provision of habitat connectivity for the species
- Commitment 9 to secure a minimum of 570 ha of important habitat for the Koala as an offset under the Plan
- Commitment 10 to establish the Georges River Koala Reserve. This includes an action undertake restoration of up to 80 ha of cleared land to increase Koala habitat. Note that this reserve will contain up to approximately 1,800 ha of habitat for the Koala
- Commitment 12 to protect Koala corridors in the Cumberland subregion, including those along the Nepean River, Georges River, Cataract River and Ousedale Creek
- Commitment 13, Action 4, to deliver ecological restoration to restore Koala habitat in the Georges River Koala Reserve and other priority areas including Ouesdale Creek and around Appin
- Commitment 20, Action 4, to invest in the NSW Koala Strategy to raise awareness of the Southern Sydney Koala population and encourage community participation in Koala conservation
- Commitment 22, Action 2, to support NSW Government programs for research that increases ecological knowledge of the Southern Sydney Koala population
- Commitment 23 to support rehabilitation measures to help maintain Koala health and welfare

Appendix E of the Plan also includes a range of Koala-specific measures to manage threats to the species. These include:

- Measures to protect Koalas during construction and land clearing operations
- Measures to ensure the integrity of Koala exclusion fencing where linear infrastructure occurs
- Measures to ensure that habitat connectivity within Koala habitat corridors is maintained
- Measures to minimise the risk of road mortality to Koalas
- Measures to minimise the level of threat posed by urban areas to Koalas, and which reduce the likelihood that Koalas would enter urban areas
- Measures to minimise the risk of spread of diseases which can impact Koala habitat (such as Phytophthora)

IMPLEMENTATION PROCESS FOR MITIGATION MEASURES

The key mechanisms or processes to implement mitigation measures to address the indirect impacts of the development under the Plan on Koala are:

- DCPs, implemented through the standard development application process under the EP&A Act
- Infrastructure guideline, implemented through future environmental assessment processes under the EP&A Act
- Koala exclusion fencing – a program administered by the Department

Additional mechanisms or processes to implement Koala mitigation measures will also be implemented under the Plan. For detailed information on the Plan's implementation, refer to Part 2.

The assessment of the indirect impacts of the urban and industrial development and infrastructure on koala in section 15.7 led to the identification of several mitigation measures that apply to koala in certain locations.

These mitigation measures are identified in Appendix E of the Plan and section 15.8 of this Assessment Report.

Development Control Plans

The key mechanism to implement mitigation measures to address the indirect impacts of the urban and industrial development on Koala is DCPs. The process for preparing and implementing DCPs is described in section 15.6.1.

DCPs will be prepared for each nominated area and will set out development controls to address indirect impacts on Koala. The development controls in DCPs will be implemented through the standard development application process under the EP&A Act that occurs prior to urban and industrial development proceeding.

The Department has prepared a DCP template that provides model provisions to help ensure the mitigation measures identified in the Plan are incorporated into DCPs and applied consistently across the nominated areas. The DCP template includes the specific controls for Koala identified in Appendix E of the Plan and section 15.8.

Infrastructure guideline

The key mechanism to implement mitigation measures to address the indirect impacts of infrastructure on Koala is the infrastructure guideline. The infrastructure guideline is described further in section 15.6.2.

The infrastructure guideline will set out development controls to address indirect impacts on Koala. The development controls in the infrastructure guideline will be implemented through future environmental assessment and approval processes under the EP&A Act that will apply to each infrastructure project prior to it proceeding.

The Department will prepare the infrastructure guideline under clause 228 of the EP&A Regulation.

The infrastructure guideline must be taken into account when public authorities consider the likely impact of infrastructure on the environment under the EP&A Act. The guideline supports implementation of the Plan by ensuring the mitigation measures in the Plan are considered and implemented through the future environmental assessment and approval processes under the EP&A Act that will be undertaken for each infrastructure project.

Part 3.3 of the infrastructure guideline applies to infrastructure proposed under Part 5 of the EP&A Act on urban capable land. It identifies mitigation requirements that must be addressed to ensure consistency with the Plan's requirements for mitigating the indirect impacts of infrastructure projects on Koala. The guideline includes:

- Objectives that align with the commitments in the Plan, including Commitment 7, to address indirect impacts
- A set of mitigation measures relevant to addressing the indirect impacts of infrastructure on Koala. These measures have been identified through this Assessment Report (see section 15.8) and are reflected in Appendix E of the Plan

Koala exclusion fencing

Koala exclusion fencing will be implemented through a program administered by the Department and funded under the Plan. The program will include a feasibility study (Commitment 7, Action 2) to help inform the design, locations, and construction of the fencing. Exclusion fencing will separate Koalas from urban capable land.

The exact location of exclusion fencing will be determined during implementation of the Plan and will be informed by the feasibility study and advice from the koala working group.

Further details of the fencing program are provided in sub plan B.

15.7 ASSESSMENT OF POTENTIAL INDIRECT IMPACTS

The potential indirect impacts from the urban, industrial, infrastructure, intensive plant agriculture and transport development on each NSW-listed species and TEC are assessed in this section.

Note that the location of infrastructure within the urban capable land is not yet known and will be determined through future planning processes. Infrastructure was therefore assessed as part of a single urban capable land footprint that includes the urban and industrial development and intensive plant agriculture.

This assessment considered:

- The nature, extent, and duration of relevant indirect impacts, as described in Section 15.4
- The general mitigation measures to address indirect impacts, where these are relevant to a species or TEC
- Likely presence/abundance of species and TEC and importance of the location at a local and regional scale
- Life history traits and susceptibility of the species and TEC to the indirect impact
- Location of the species and TEC relative to the likely extent of the indirect impact
- Amount and quality of un-impacted habitat remaining
- Levels of existing protection

A conclusion is provided about whether any residual risks remain for each species and TEC. Additional species or TEC specific mitigation measures under the Plan to address residual risks are described in Section 15.8.

The assessment of potential indirect impacts is set out in the following tables:

- Fauna – Table 15-17
- Flora – Table 15-18
- TECs – Table 15-19

This section covers the assessment of indirect impacts on NSW-listed TECs and species as required under the BAM. Detailed assessments of the potential indirect impacts on each Commonwealth-listed TEC and species, as well as other EPBC Act protected matters, are undertaken in the following chapters:

- Chapter 29 – Commonwealth-listed flora
- Chapter 30 – Commonwealth-listed fauna
- Chapter 31 – Commonwealth-listed TECs
- Chapter 32 – Migratory species
- Chapter 33 – Ramsar wetlands
- Chapter 34 – World and National Heritage
- Chapter 35 – Commonwealth Land

15.7.1 FAUNA

Table 15-17: Assessment of indirect impacts – fauna

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
BIRDS							
Anthochaera phrygia	Regent Honeyeater	CE	CE	ECS SCS	Removal of trees and firewood collection Spread of weeds Inappropriate fire regimes	The Regent Honeyeater is endemic to the south-eastern Australian mainland with a distribution from south-east Queensland to central Victoria. However, the species only regularly breeds at four locations: Bundarra-Barraba (NSW), Capertee Valley (NSW) and Hunter Valley (NSW), and the Chiltern area (VIC) (DoE, 2016). Its breeding areas generally consist of a nest tree and surrounding food sources, and its breeding times and, similarly, movement patterns are correlated with the flowering of certain eucalypt and mistletoe species (DoE, 2015a). While generally associated with box ironbark eucalypt woodland and dry sclerophyll forest, the species has also been found in riparian corridors with she-oak (*Casuarina* spp.) The Regent Honeyeater occurs throughout the Strategic Assessment Area with the majority of records associated with the larger patches of vegetation towards the north. There are a total of 92 records within the Strategic Assessment Area Until very recently, all records related to foraging birds. However, at the end of 2019 a pair was observed successfully breeding near Mulgoa at Fernhill Estate, just west of the boundary between the WSA and GPEC. The nest was recorded in vegetation mapped as Shale Sandstone Transition Forest. It is connected to the much broader areas of intact vegetation west of the Strategic Assessment Area; although the nest site itself is towards the interface of this vegetation and cleared rural land. The site is protected and managed in perpetuity under a biobanking agreement The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the specific risk relating	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						to the removal of large mature trees that the species is reliant upon may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, an additional specific mitigation measure has been identified to mitigate residual risks to this species	
Artamus cyanopterus cyanopterus	Dusky Wood-swallow	N/A	V	ECS	Weed invasion	Within Australia, the Dusky Wood-swallow is widespread in eastern, southern, and south-western Australia. The species occurs throughout most of NSW, and breeding occurs on the western slopes of the Great Dividing Range. The species' primary habitat consists of dry, open eucalypt forests and woodlands with an open or sparse understory and groundcover of grasses or sedges and fallen woody debris. The diet consists of invertebrates, mainly insects that are captured from both above and under the canopy or over water. There is some evidence of site fidelity for breeding (OEH, 2017g) Records of the species occur throughout the Cumberland Plain subregion but are similarly widespread across NSW (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
Botaurus poiciloptilus	Australasian Bittern	E	E	ECS	Hydrological changes Predation by introduced vertebrates Weed invasion Inappropriate fire regimes	The Australasian Bittern occurs in Australia, New Caledonia, and New Zealand. Within NSW, the Australasian Bittern is found along the coast and has been recorded in the Murray-Darling Basin and the Cumberland subregion (TSSC, 2019). The species inhabits shallow freshwater or brackish swamps with a preference for the presence of sedges, rushes, and reeds (Garnett et al., 2011). Nests are built on a bed of reeds in densely-vegetated wetlands and placed approximately 30 cm above the water level (TSSC, 2019) There are five records of the species within the Strategic Assessment Area: • Four occur at Pitt Town Lagoon in the north of the Strategic Assessment Area near to the Hawkesbury River (approximately 15 km from the nearest development area) • One occurs near Wianamatta (South Creek) in Oran Park (approximately 9 km from the nearest development area) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Most records of the species surround the subregion, and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including hydrological changes, predation, weed invasion, inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	No
Calidris ferruginea	Curlew Sandpiper	CE Mig.	E	ECS	None	The Curlew Sandpiper occurs along most of Australia's coast and the entire coast of NSW, particularly in the Hunter Estuary and occasionally in freshwater wetlands in the Murray-Darling Basin. The species breeds in Siberia and migrates to Australia, as well as Africa and Asia, for the non-breeding period (OEH, 2021b)	N/A

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						The species generally inhabits littoral and estuarine habitats. In NSW, the species is mainly found in intertidal mudflats of sheltered coasts (OEH, 2021b) The majority of records in the Cumberland Plain subregion are concentrated around Parramatta and north of Penrith, east of Kurrajong (OEH, 2021a) As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	
Callocephalon fimbriatum	Gang-gang Cockatoo	N/A	V	ECS SCS	Inappropriate hazard reduction burns Weed invasion	The Gang-gang Cockatoo occurs from southern Victoria through south- and central-eastern New South Wales. In NSW, the species is distributed from the south-east coast to the Hunger region and inland to the Central Tablelands and south-west slopes (OEH, 2017n) In spring and summer, the species is found in tall mountain forests and woodlands, particularly in heavily timbered and mature wet sclerophyll forests. In autumn and winter, the species moves to lower altitudes in drier, more open, eucalypt forests and woodlands or in dry forest in coastal areas and in urban areas. For nesting and roosting, the species favours old growth forest and woodland attributes (OEH, 2017n) Records are sparsely scattered across the Cumberland Plain subregion and more heavily concentrated in areas outside the boundary (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Most records of the species surround the subregion, and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
Calyptorhynchus lathami	Glossy Black-cockatoo	N/A	V	ECS SCS	Loss of hollow bearing trees due to land management Weed invasion	The Glossy Black-cockatoo is uncommon but widespread from the central Queensland coast to East Gippsland in Victoria and inland to the southern tablelands and central western plains of NSW. The species' primary habitat is open forest and woodlands of the coast and the Great Dividing Range where strands of she-oak occur. The species exclusively feeds on species of she-oak (OEH, 2017o) There are a few records in the Cumberland Plain subregion, although most are distributed outside the boundary (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Most records of the species surround the subregion, and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	No
Chthonicola sagittata	Speckled Warbler	N/A	V	ECS	Weed invasion Nest failure due to predation by native and non-native birds, cats, dogs, and foxes	The Speckled Warbler has a patchy distribution throughout south-eastern Queensland, the eastern half of NSW and into Victoria. The species is found in the hills and tablelands of the Great Dividing Range. Primary habitat includes a wide range of *Eucalyptus* dominated communities that have a grassy understorey. The species are often found on rocky ridges or in gullies. Breeding pairs are sedentary and occupy a territory of approximately 10 ha with a slightly larger home-range when not breeding (OEH, 2017aa) Records are scattered throughout the western part of the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because many records of the species surround the subregion or occur in protected lands in the subregion, and the subregion does not appear to be a stronghold for the species As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and predation. These measures are expected to manage any residual impacts to the species	
Circus assimilis	Spotted Harrier	N/A	V	ECS	Loss of mature trees from rural landscapes Secondary poisoning from the use of pindone in rabbit control and rodenticides	The Spotted Harrier occurs throughout the Australian mainland, except in densely forested or wooded habitats of the coast, escarpment, and ranges, and rarely in Tasmania. In NSW, individuals are widely dispersed and comprise a single population. The species is found in grassy open woodland, including Acacia and mallee remnants, inland riparian woodland, and grassland and shrub steppe. Primary habitat is native grassland but is also found in agricultural land (OEH, 2017ab) Records are sparse across the Cumberland Plain subregion with the majority in the northwest area and a few in the south (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas This species is reliant on mature trees and at risk from secondary poisoning. There is a risk that these issues may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	Yes
Climacteris picumnus victoriae	Brown Treecreeper	N/A	V	ECS	Weed invasion Degradation of habitat, particularly loss of tree hollows	The Brown Treecreeper is endemic to eastern Australia and occurs in eucalypt forests and woodlands of inland plains and slopes of the Great Dividing Range. The eastern subspecies lives in eastern NSW in eucalypt woodlands through central NSW and in coastal areas with drier open woodlands, such as the Snowy River Valley, Cumberland Plains, Hunter Valley, and parts of the Richmond and Clarence Valleys (OEH, 2017c) The species is considered mostly sedentary and mainly found in woodlands dominated by stringybarks or other rough-barked eucalypts, usually with an open	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						grassy understory. Breeding occurs in pairs or co-operatively in territories which range in size from 1.1 to 10.7 ha (OEH, 2017c) Records are sparsely scattered in the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion • The subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. In addition, there is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Brown Treecreeper. These measures are expected to manage any residual impacts to the species	
Daphoenositta chrysoptera	Varied Sittella	N/A	V	ECS	Weed invasion Inappropriate fire regimes	The Varied Sittella occurs throughout most of mainland Australia except in treeless deserts and open grasslands. In NSW, the species' distribution is nearly continuous from the coast to the far west. Primary habitat includes eucalypt forests and woodlands, especially those containing rough-barked species and mature smooth-barked gums with dead branches, mallee, and *Acacia* woodland. The species feeds on arthropods gleaned from crevices in mostly dead, tree bark. Nesting occurs in upright tree forks high in the living tree canopy and often re-uses the same fork or tree in successive years (OEH, 2017af) Records occur throughout the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because:	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						• Records occur throughout the bioregion • Many records in the subregion occur in protected lands • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	
Ephippiorhynchus asiaticus	Black-necked Stork	N/A	E	ECS	Modification or degradation of wetlands	The Black-necked Stork is found in Australia and New Guinea with another subspecies in India and south-east Asia. In Australia, the species is widespread in coastal and subcoastal northern and eastern Australia but rarely occurs south of Sydney. In NSW, the species inhabits floodplain wetlands of the major coastal rivers. Storks usually forage in water 5-30 cm deep for vertebrate and invertebrate prey and nest in tall trees close to water. Breeding territories are large and variable in size (OEH, 2017b) Records are sparsely spread across the Cumberland Plain subregion with a few concentrated in the Penrith area (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion; the subregion doesn't appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species,	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						including impacts to hydrological processes. These measures are expected to manage any residual impacts to the species	
Epthianura albifrons	White-Fronted Chat	N/A	V	ECS	None	The White-Fronted Chat is endemic to Australia and distributed across the southern half of Australia from southern Queensland to southern Tasmania. The species is found in mostly temperate to arid climates in foothills and lowlands up to 1000 m above sea level. In NSW, the species occurs mostly in the southern half of the state in damp open habitats along the coast and near waterways in the western part of the state. Foraging occurs on bare or grassy ground in wetland areas, feeding mainly on flies and beetles caught from or close to the ground. Nests are built in low vegetation, generally about 23 cm above the ground (OEH, 2017ag) A few records occur near the edges of the Cumberland Plain subregion with a concentration in Parramatta (OEH, 2021a) While the Plan has the potential to exacerbate several threats to the species, this species is unlikely to be indirectly impacted because the species is wide-ranging with areas of habitat (as indicated by records) occurring some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A
Glossopsitta pusilla	Little Lorikeet	N/A	V	ECS	Weed invasion Inappropriate fire regimes Loss of old hollow-bearing trees	The Little Lorikeet is found across the coastal and Great Divide regions of eastern Australia from Cape York to South Australia. Foraging occurs primarily in the canopy of open *Eucalyptus* forest and woodland but also in *Angophora*, *Melaleuca*, and other tree species, particularly in riparian habitats. Roosting occurs in treetops distanced from feeding areas, while nesting generally occurs close to feeding areas in the limb or trunk of smooth-barked eucalypts. These nesting sites are repeatedly used for decades with a preference for riparian trees (OEH, 2017u) Records are widespread throughout the Cumberland Plain subregion but primarily along riparian corridors (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the specific risk relating to the removal of old hollow bearing trees that the species is reliant upon may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, an additional specific mitigation measure has been identified to mitigate residual risks to this species	
Grantiella picta	Painted Honeyeater	V	V	ECS	None	The Painted Honeyeater is distributed across and breeds on the inland slopes of the Great Dividing Range in NSW, Victoria, and southern Queensland. Primary habitat includes *Acacia pendula*, *A. harpophylla*, and box-gum woodlands and box-ironbark forests. The species is a specialist and only feeds on the fruits of mistletoes growing on woodland eucalypts and acacias with a preference for the mistletoes of *Amyema*. Nesting occurs in the outer canopy of drooping eucalypts, she-oak, paperbark, or mistletoe branches (OEH, 2017w) Four records exist towards the north of the Cumberland Plain subregion (OEH, 2021a) While the Plan has the potential to exacerbate several threats to the species, this species is unlikely to be indirectly impacted because: • the species is wide-ranging • there are few records within the subregion, all associated with habitat (as indicated by records) that occurs some distance away from the urban capable land and transport corridors and which is unlikely to be subject to indirect impacts	N/A
Haliaeetus leucogaster	White-bellied Sea-Eagle	N/A	V	ECS SCS	Reduction of suitable nesting habitat Non-target poisoning during vertebrate pest control	The White-bellied Sea-Eagle is distributed across the Australian coastline and well inland along rivers and wetlands of the Murray Darling Basin. In NSW, the species is widespread along the east coast and major inland rivers and waterways. Habitats are characterised by the presence of large areas of open water including larger rivers, swamps, lakes, and the sea. The species breeds in mature tall open forest, open forest, tall woodland, and swamp sclerophyll forest near foraging habitat. Nest trees are typically large emergent eucalypts (OEH, 2019r)	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
					Disturbance by humans or human activity when nesting	Records are distributed throughout the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. In particular, development controls to establish ecological setbacks between development and raptor nests These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, there is a risk that issues relating to mature trees and secondary poisoning may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	
Hieraaetus morphnoides	Little Eagle	N/A	V	ECS SCS	Degradation of breeding habitat Secondary poisoning from rabbit baiting	The Little Eagle is found throughout the Australian mainland except in the most densely forested parts of the Dividing Range escarpment. The species inhabits open eucalypt forest, woodland, or open woodland in addition to she-oak or *Acacia* and riparian woodlands. Nesting occurs in tall living trees (OEH, 2017t) Records are distributed throughout the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas This species is reliant on mature trees and at risk from secondary poisoning, and there is a risk that these issues may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	Yes
Irediparra gallinacea	Comb-crested Jacana	N/A	V	ECS	Loss and degradation of wetland habitat Predation on breeding birds and their nests by feral	Globally, the species is found in Australia, Borneo, the Philippines, and other Pacific Islands. In Australia, the species is distributed across northern and eastern Australia in coastal and subcoastal regions. Primary habitat includes permanent freshwater wetlands, either still or slow-flowing, with a good surface cover of floating vegetation or fringing and aquatic vegetation (OEH, 2018d)	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
					predators such as the European red fox	A few records exist along the north-western boundary of the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes and predation. These measures are expected to manage any residual impacts to the species	
Ixobrychus flavicollis	Black Bittern	N/A	V	ECS	Impacts to riparian vegetation Predation by foxes and feral cats	The Black Bittern is distributed from southern NSW north to Cape York and along the north coast to the Kimberley region. The species is also found in the south-west of WA. In NSW, the Black Bittern is scattered along the east coast. Primary habitat includes both terrestrial and estuarine wetlands, generally in areas of permanent water and dense vegetation. Roosting occurs in trees or on the ground amongst dense reeds (OEH, 2018c) Records are sparsely distributed across the Cumberland Plain subregion with the majority found near Kurrajong near the north-western boundary (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species is wide-ranging, and the subregion does not appear to be a stronghold for the species • Many records in the subregion occur in existing conservation areas	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to riparian vegetation and predation. These measures are expected to manage any residual impacts to the species	
Lathamus discolor	Swift Parrot	CE	E	ECS SCS	Collision mortality Inappropriate fire regimes Predation by feral cats	The Swift Parrot breeds in Tasmania in summer and migrates to mainland Australia in winter. On the mainland, the species occurs in Victoria and eastern NSW but may also be found in south-eastern Queensland or south-eastern South Australia. In NSW, the species forages in forests and woodlands throughout the coastal and western slopes regions (TSSC, 2016a). The species forages on flowers, seeds, fruit, and psyllid lerps in *Eucalyptus* species with a preference for larger trees, which provide more reliable resources than younger trees (Saunders & Tzaros, 2011). Its distribution is primarily determined by food availability and the presence of non-aggressive competitors (Saunders & Heinsohn, 2008) Within the Recovery Plan, the Hawkesbury-Nepean and Sydney Metro Catchment Management Authority areas (which contain the Strategic Assessment Area) are identified as localities which are likely to contain priority habitats (Saunders & Tzaros, 2011) The species has been recorded throughout the Cumberland subregion and is associated with flowering woodland areas. There are 266 BioNet records within the Strategic Assessment Area with records ranging from the early 1900s to the present day The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land in the nominated areas and transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the species benefits from the feeding resources associated with large mature trees, an additional	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						specific mitigation measure has been identified to mitigate residual risks to this species	
Limicola falcinellus	Broad-Billed Sandpiper	N/A	V	ECS	None	After breeding in northern Siberia, the Broad-Billed Sandpiper migrates to Australia. In Australia, the birds are found along the northern and, occasionally, southern coast. In NSW, the species primarily occurs in the Hunter River estuary. Primary habitat includes sheltered parts of the coast, including estuarine sandflats and mudflats, harbours, embayments, lagoons, saltmarshes, and reefs. Roosting occurs on banks on sheltered sand, shell, or shingle beaches. Foraging occurs in the soft, wet mud (OEH, 2019e) The species has not previously been recorded in the Cumberland Plain subregion (OEH, 2021a) While the Plan has the potential to exacerbate several threats to the species, this is unlikely to result in indirect impacts to the species because there are no records of the species in the subregion and areas of habitat (as indicated by records) occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A
Limosa limosa	Black-tailed Godwit	Mig.	V	ECS	None	The Black-tailed Godwit breeds in Mongolia and Eastern Siberia and flies to Australia for the southern summer. In NSW, the species is most frequently found at Kooragang Island with occasional records along the coast and inland. The bird primarily inhabits sheltered bays, estuaries, and lagoons with large intertidal mudflats and/or sandflats. Inland, the species is found on mudflats and in water less than 10 cm deep around muddy lakes and swamps. Foraging occurs in soft mud or shallow water (OEH, 2019d) There are few records within the Cumberland Plain subregion scattered in Kurrajong and Parramatta (OEH, 2021a) As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	N/A
Lophoictinia isura	Square-tailed kite	N/A	V	ECS SCS	Disturbance to or removal of	The Square-tailed Kite is distributed along the coastal and subcoastal areas of Australia. In NSW, the species occurs along the major west-flowing river systems and migrates to the south-east to breed in the summer. The bird primarily inhabits	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
					potential nest trees near watercourses Secondary poisoning	timbered areas including dry woodlands and open forests with a preference for timbered watercourses. The species is a specialist hunter of passerines and insects in the tree canopy (OEH, 2017ac) Records occur throughout the Cumberland Plain subregion with a greater concentration in the northern half (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. In particular, development controls to establish ecological setbacks between development and raptor nests These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, this species is reliant on mature trees for nesting and is at risk from secondary poisoning, and there is a risk that these issues may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	
Melanodryas cucullata cucullata	Hooded Robin (South-Eastern Form)	N/A	V	ECS	Weed invasion Inappropriate fire regimes	The Hooded Robin is distributed across Australia except in the driest deserts and wetter coastal areas. The species is mostly sedentary but local seasonal movements are possible. The south-eastern form occurs from Brisbane to Adelaide and throughout much of inland NSW. Primary habitat includes lightly wooded country that is structurally diverse (OEH, 2017s) Sparse records occur in the southern part of the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species is wide-ranging and records occur throughout the bioregion	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						• The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	
Melithreptus gularis gularis	Black-Chinned Honeyeater (Eastern subsp.)	N/A	V	ECS	Weed invasion Inappropriate fire regimes Removal of large trees	The Black-Chinned Honeyeater occurs in Queensland, NSW, Victoria, and rarely in South Australia. In NSW, the species is found in the tablelands and western slopes of the Great Dividing Range to the north-west and central-west plains and the Riverina. Primary habitat includes mostly upper levels of drier open forests or woodlands dominated by box and ironbark eucalypts. The species is found in large woodland patches with home ranges of at least 5 hectares. Nesting occurs high in the crown of a tree in the uppermost lateral branches (OEH, 2017a) Records are scattered throughout the Cumberland Plain subregion. The majority concentrated in Penrith and Kurrajong (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, there is a risk that issues associated with the removal of large trees may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
Neophema pulchella	Turquoise Parrot	N/A	V	ECS	Loss of hollow-bearing trees and critical habitat feature degradation Weed invasion Inappropriate fire regimes Predation by foxes and cats	from the coastal plains to the western slopes of the Great Dividing Range. The species inhabits the edges of eucalypt woodland adjoining clearings, timbered ridges, and creeks in farmland. Foraging for seeds or grasses and herbaceous plants occurs on the ground. Nesting occurs in tree hollows, logs, or posts (OEH, 2017ae) Scattered records are located throughout the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species is wide-ranging, and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion, inappropriate fire regimes and predation. In addition, there is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Turquoise Parrot. These measures are expected to manage any residual impacts to the species	No
Ninox connivens	Barking Owl	N/A	V	ECS SCS	Removal of old, hollow-bearing trees	The Barking Owl is widespread throughout mainland Australia except for the central arid regions. Core populations exist on the western slopes and plains and in some northeast coastal and escarpment forests. The species inhabits woodland and open forest, including fragmented remnants and partly cleared farmland. Hunting can extend into closed forest and more open areas, but large permanent territories are required due to sparse prey densities (OEH, 2019b) Records in the Cumberland Plain subregion are concentrated in and around Parramatta with a few dispersed across the rest of the subregion (OEH, 2021a)	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC There is a risk that issues associated with the removal of large trees may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	
Ninox strenua	Powerful Owl	N/A	V	ECS SCS	Loss of hollow-bearing trees High frequency hazard reduction burning Predation of fledglings by foxes, dogs, and cats	The Powerful Owl is endemic to eastern and south-eastern Australia, primarily on the coastal side of the Great Dividing Range from Mackay to south-western Victoria. In NSW, the species is widely distributed throughout the eastern forests from the coast inland to tablelands. The species inhabits a range of vegetation types from woodland and open sclerophyll forests to tall open wet forest and rainforest. The owl requires large tracts of forest or woodland habitat but can occur in fragmented landscapes as well. Powerful Owls nest in large tree hollows, in large, old eucalypts (OEH, 2019p) Records occur throughout most of the Cumberland Plain subregion in relatively high concentrations (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, there is a risk that issues associated with the removal of large, mature trees may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	Yes
Pandion cristatus	Eastern Osprey	N/A	V	ECS	None	The Eastern Osprey is distributed across Indonesia, Australia, and New Caledonia. In Australia, the species is found along the coastline except for Victoria and Tasmania and is uncommon to rare or absent from closely settled parts of south-eastern	N/A

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						Australia. Primary habitat includes coastal areas, especially the mouths of large rivers, lagoons, and lakes (OEH, 2018f) Records in the Cumberland Plain subregion occur in Parramatta (OEH, 2021a) While the Plan has the potential to exacerbate several threats to the species, this is unlikely to result in indirect impacts to the species because the species favours coastal areas and usually nests within 1 km of the coast. The majority of areas of habitat (as indicated by records) occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	
Petroica boodang	Scarlet Robin	N/A	V	ECS	Weed invasion Predation by feral cats (*Felis catus*)	The Scarlet Robin is distributed from Queensland to South Australia, Tasmania, and Western Australia. In NSW, the species is found from the coast to the inland slopes. After breeding, populations may disperse to the lower valleys and plains of the tablelands and slopes. Primary habitat includes dry eucalypt forests and woodlands with an open and grassy understorey. The species is typically found in both mature and regrowth vegetation. Breeding occurs on ridges, hills, and foothills of the western slopes, the Great Dividing Range and eastern coastal regions (OEH, 2017z) Records are scattered across the Cumberland Plain subregion with the majority in the northern portion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion; the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and predation. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
Petroica phoenicea	Flame Robin	N/A	V	ECS	Weed invasion	The Flame Robin is endemic to south-eastern Australia and ranges from Queensland to South Australia and Tasmania. In NSW, the species breeds in upland areas, and, in winter, many birds move to the inland slopes and plains. Breeding occurs in upland tall moist eucalypt forests and woodlands often on ridges and slopes with a preference for clearings or areas with open understoreys (OEH, 2017l) Sparse records are scattered across the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to increase weed invasion in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion; the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	No
Rostratula australis	Australian Painted Snipe	E	E	ECS	Loss or degradation of wetlands Predation by feral animals Vegetation changes caused by introduced plants Inappropriate fire regimes	The Australian Painted Snipe is only found in Australia and mainly occurs in the Murray Darling Basin (DoEE, 2019; DSEWPC, 2013). Other important areas for this species include Queensland Channel Country, Fitzroy Basin of Central Queensland, south-eastern South Australia, and adjacent parts of Victoria (DSEWPC, 2013) Its habitats include both ephemeral and permanent shallow freshwater and, occasionally, brackish wetlands. The species is often found in dense covers of grass and reeds (DSEWPC, 2013). Breeding occurs year-round depending on the availability of suitable wetland conditions. The species feeds on vegetation, seeds, and invertebrates (DoEE, 2018c) There are two records for the Australian Painted Snipe within the Strategic Assessment Area in the last sixteen years. One is within GPEC from an unnamed water body outside of the urban capable land near to Wianamatta, and the other is	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						from the north of the Strategic Assessment Area in the floodplain of the Hawkesbury River. While two records occur in the Strategic Assessment Area, the area is not recognised as a key location for the species and the nominated areas include only one record (within GPEC) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species occurs elsewhere in the bioregion, with relatively few records in the subregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, predation, weed invasion and inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	
Stagonopleura guttata	Diamond Firetail	N/A	V	ECS	Weed invasion	The Diamond Firetail is endemic to south-eastern Australia from Queensland to South Australia. The species is widely distributed in NSW and found in grassy eucalypt woodlands, open forest, mallee, natural temperate grassland, and secondary grassland derived from other communities. The firetail feeds exclusively on the ground on ripe and partly-ripe grass, herb seeds, green leaves, and insects (OEH, 2017e) A few records are found in the Cumberland Plain subregion with the majority concentrated in Picton (OEH, 2021a) The Plan has the potential to increase weed invasion in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						• The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	
Stictonetta naevosa	Freckled Duck	N/A	V	ECS	Hydrological disturbance	The Freckled Duck is distributed across south-eastern and south-western Australia. Breeding occurs in large temporary swamps created by floods in the Bulloo and Lake Eyre basins and the Murray-Darling system, particularly along the Paroo and Lachlan Rivers, and other rivers within the Riverina. Primary habitat consists of permanent freshwater swamps and creeks with heavy growth of Cumbungi, Lignum, or Tea-tree. During drier times, the duck will move from ephemeral breeding swamps to more permanent water sources (OEH, 2017m) A few records exist in the Cumberland Plain subregion with the majority found in Kurrajong (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; there are very few recent records in the subregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including hydrological disturbance. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
Tyto novaehollandiae	Masked Owl	N/A	V	ECS SCS	Loss of mature hollow-bearing trees	The Masked Owl is found from the coast to the western plains in Australia. The species is widespread across NSW with no seasonal variation in its distribution. Its primary habitat includes dry eucalypt forests and woodlands. Hunting occurs along the edges of forests, including roadsides. The owl roosts and breeds in moist eucalypt forested gullies, where it uses large tree hollows and sometimes caves (OEH, 2019l) Records are scattered across the Cumberland Plain subregion with the majority of records occurring along the boundary (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas This species is reliant on mature trees and the specific measure in Table 15-20 to retain large trees may benefit the species to some extent, particularly in areas adjacent to large patches of potential habitat. This is expected to manage any residual impacts to the species However, there is a risk that issues associated with the removal of large, mature trees may not be adequately addressed through the general mitigation measures described in Section 15.6. Therefore, specific mitigation measures have been identified to mitigate potential residual impacts	Yes
MAMMALS							
Cercartetus nanus	Eastern Pygmy-possum	N/A	V	SCS	Changed fire regimes that affect the abundance of flowering proteaceous and myrtaceous shrubs Predation from cats, dogs, and foxes Road mortality	The Eastern Pygmy-possum occurs in south-eastern Australia, including Tasmania. In NSW, the species is found along the coast and inland to the western slopes. Habitats range from rainforest through sclerophyll forest and woodlands to heath. The pygmy-possum feeds mostly on nectar and pollen collected from banksias, eucalypts, and bottlebrushes and serves as an important pollinator of heathland plants, such as banksias. When flowers are unavailable, the species relies on soft fruits and insects (OEH, 2017j) There are three records in Kurrajong in the Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation However, the species would benefit from strengthened measures that specifically reflect the species reliance on nectar and pollen from Proteaceae shrubs and the risks of predation from cats. Therefore, additional specific mitigation measures have been identified to mitigate residual risks to this species	
Chalinolobus dwyeri	Large-eared Pied Bat	V	V	SCS	Disturbance of roosts from human recreational activities Fire in the proximity of roosts	The Large-eared Pied Bat occurs from Shoalwater Bay in south Queensland to Ulladulla in south-eastern NSW. Within NSW, the species is found in areas of volcanic strata in the north-east at Coolah Tops, Mt Kaputar, and Warrumbungle National Park and in sandstone areas of the Sydney Basin and the western slopes and plains including Pilliga Nature Reserve. Its habitat includes well-timbered areas and low to mid-elevation dry open forests and woodland (DERM, 2011) The species requires highly specific nursery roosts with deep roofs that allow juveniles to learn to fly and roof indentations that capture heat. Its preferred roosting locations include sandstone caves, crevices in cliffs, old mine workings, and disused mud nests of the Fairy Martin (*Petrochelidon ariel*) (DERM, 2011). The species has high site fidelity and will visit the same maternity site over many years (OEH, 2019i) There are 65 records for the species within the Strategic Assessment Area. The records occur along the boundary of the Strategic Assessment Area in the south (where the largest cluster of records occurs within Wilton), east and west and are generally associated with areas of sandstone geology. These records are all considered to form part of a single population and which, more broadly, form part of the important population associated with the sandstone escarpments of the Sydney Basin The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land in the nominated areas and transport corridors. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species occurs across the bioregion, the subregion does not appear to be a stronghold for the species • There are no known roost or breeding sites close to areas at risk of indirect impacts from the development	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including disturbance and increased fire risk. These measures are expected to manage any residual impacts to the species	
Dasyurus maculatus maculatus (SE mainland population)	Spot-tailed Quoll, Spotted-tailed Quoll	E	V	ECS	Competition and predation from introduced predators Road mortality Inappropriate fire regimes	The Spot-tailed Quoll occurs in eastern Australia, including Victoria, NSW, and Queensland. The species is found in a variety of habitats, including rainforest, open forest, woodland, coastal heath, and inland riparian forest. As a nocturnal species, the Spot-tailed Quoll requires dens to shelter in during the day. The species' Recovery Plan notes that habitat critical to the survival of the species includes large patches of forest with adequate denning resources and relatively high densities of medium-sized mammalian prey, which make up the majority of their diet (DELWP, 2016; TSSC, 2020) Within the Strategic Assessment Area, records primarily occur around the edges where some level of landscape connectivity remains with the large areas of surrounding wilderness to the north and west of the Strategic Assessment Area and south of Sydney The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GMAC, Wilton, and the OSO transport corridor As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including road mortality and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the species would benefit from specific measures that reflect the risks associated with predation from cats. Therefore, additional a specific mitigation measure has been identified to mitigate residual risks to this species	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
Falsistrellus tasmaniensis	Eastern False Pipistrelle	N/A	V	ECS	Loss of roosting habitat, primarily hollow-bearing eucalypts	The Eastern False Pipistrelle occurs on the south-east coast and ranges of Australia from southern Queensland to Victoria and Tasmania. The species prefers moist habitats with trees taller than 20 m. Roosting generally occurs in eucalypt hollows but also under loose bark on trees or in buildings (OEH, 2017i) Records are distributed across the Cumberland Plain subregion with a heavy concentration between Parramatta and Penrith (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC This species is reliant on mature, hollow bearing trees and would benefit from strengthened measures to protect this habitat. Therefore, a specific mitigation measure has been identified to mitigate potential residual impacts	Yes
Micronomus norfolkensis	Eastern Coastal Free-tailed Bat	N/A	V	ECS	Loss of hollow-bearing trees Artificial light sources spilling on to foraging and/or roosting habitat Hazard reduction burns on foraging and/or roosting habitat	The Eastern Coastal Free-tailed Bat occurs along the east coast from southern Queensland to southern NSW. Primary habitat includes dry sclerophyll forest, swamp forests, and mangrove forests east of the Great Dividing Range. Roosting generally occurs in tree hollows but also under bark or in man-made structures (OEH, 2020b) Records are widespread throughout the entire Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including light pollution and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, additional specific measures have been identified to reflect the species reliance on large mature trees and man-made structures for roosting and address potential residual impacts to these features	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
Miniopterus australis	Little Bent-wing Bat	N/A	V	ECS	Disturbance to and loss of known maternity and roost sites such as caves, and roosts within culverts, tunnels and under bridges Hazard reduction fires Predation from cats and foxes	The Little Bent-wing Bat is distributed across the east coast and ranges of Australia from Queensland to NSW. The species inhabits moist eucalypt forest, rainforest, vine thicket, wet and dry sclerophyll forest, Melaleuca swamps, dense coastal, and banksia scrub. Roosting occurs in caves, tunnels, tree hollows, abandoned mines, stormwater drains, culverts, bridges, and occasionally buildings. In NSW, the largest maternity colony is in close association with a large maternity colony of Eastern Bent-wing Bats and may depend on the large colony to provide the high temperatures needed to rear its young (OEH, 2020e) Records are scattered across the Cumberland Plain subregion with a heavy concentration in north-eastern Parramatta (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, specific measures are needed to reflect the species reliance on large mature trees and man-made structures for roosting and address potential residual impacts to these habitat features	Yes
Miniopterus orianae oceanensis	Large Bent-winged Bat	N/A	V	ECS	Disturbance by general public accessing caves and adjacent areas Hazard reduction fires Predation by feral cats	The Large Bent-winged Bat is found along the east and north-west coasts of Australia. The bat primarily roots in caves but also utilises derelict mines, stormwater tunnels, buildings, and other man-made structures. The species form discrete populations centred on a maternity cave that is used annually in spring and summer for the birth and rearing of young. Maternity caves have very specific temperature and humidity regimes (OEH, 2019j) Records are densely scattered across the entire Cumberland Plain subregion and most heavily concentrated in Parramatta (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including disturbance, inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, specific measures are needed to reflect the species use of man-made structures for roosting and address potential residual impacts to these habitat features	
Myotis macropus	Southern Myotis	N/A	V	SCS	Loss or disturbance of roosting sites Reduction in stream water quality	The Southern Myotis occurs in the coastal band from the north-west of Australia across the top-end and south to western Victoria. Roosting generally occurs close to water in caves, mine shafts, hollow-bearing trees, stormwater channels, buildings, under bridges, and in dense foliage. The species forages over streams and pools to catch insects and small fish (OEH, 2020h) Records are densely scattered across the entire Cumberland Plain subregion (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including disturbance and impacts to hydrological processes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species However, specific measures are needed to reflect the species reliance on large mature trees and man-made structures for roosting and address potential residual impacts to these habitat features	Yes
Petaurus australis	Yellow-bellied Glider	N/A	V	ECS	Loss of hollow-bearing trees	The Yellow-bellied Glider occurs along the eastern coast to the western slopes of the Great Dividing Range from southern Queensland to Victoria. The species primarily inhabits tall mature eucalypt forest in areas with high rainfall and nutrient rich soils,	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						but forest type preferences vary with latitude and elevation. The glider feeds mainly on plant and insect exudates and dens in large tree hollows (OEH, 2017ai) Records are densely concentrated in the Kurrajong area of the Cumberland Plain subregion with a few in Penrith, Picton, and Parramatta (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; there are very few recent records in the subregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development). There is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Yellow-bellied Glider. These measures are expected to manage any residual impacts to the species	
Petaurus norfolcensis	Squirrel Glider	N/A	V	SCS	Loss of hollow-bearing trees Inappropriate fire regimes Road mortality	The Squirrel Glider is sparsely distributed in eastern Australia from northern Queensland to western Victoria. The species inhabits mature or old growth Box, Box-Ironbark woodlands and River Red Gum forest west of the Great Dividing Range and Blackbutt-Bloodwood forest with heath understory in coastal areas. The glider requires tree hollows for refuge and nest sites (OEH, 2017ad) There are few records distributed across Kurrajong and the southern boundary of the Cumberland Plain subregion with a couple of records near Parramatta (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; there are very few recent records in the subregion	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						• The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and road mortality. In addition, there is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Squirrel Glider. These measures are expected to manage any residual impacts to the species	
Phascolarctos cinereus	Koala	V	V	ECS SCS	Vehicle strike Effects of urban development including predation by dogs Disruption of connectivity Fire Disease (Chlamydiosis caused by infection with Chlamydia)	Koalas are distributed within coastal and inland regions of eastern Australia, from South Australia to northern Queensland. The species is a specialist folivore, highly selective of its leaf diet from only a small number of trees in their local area. Koalas eat the leaves of over 100 *Eucalyptus* species and over 30 non-*Eucalyptus* species (including genera such as *Angophora* and *Corymbia*) (OEH, 2018a) and prefer trees growing in fertile soils, which provide for higher leaf nutrient content (McAlpine et al., 2008) There are two known populations of Koalas that occur within or near to the Strategic Assessment Area. The most relevant to this assessment is the Southern Sydney population which occurs within and near to Wilton and GMAC. The other is the Blue Mountains population which has infrequent records in the western portion of the Strategic Assessment Area The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including road mortality, impacts from domestic animals and inappropriate fire regimes These measures are expected to address a number of potential indirect impacts from development under the Plan on this species. However, residual risks to the species	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						have been identified and a range of specific mitigation measures are needed to mitigate these (see section 15.6.4 and Chapter 30 for the full Koala impact assessment)	
Pteropus poliocephalus	Grey-headed Flying-fox	V	V	ECS	Camp disturbance Loss of large trees for foraging and roosting	The Grey-headed Flying-fox is typically found within 200 km of the eastern coast of Australia from Queensland to Victoria. The species roosts on exposed branches located close to water sources. Roost vegetation includes rainforest patches, stands of *Melaleuca*, mangroves, and riparian vegetation. Roosting camps are used for mating, giving birth, and rearing young. The species have high site fidelity to these roosting camps with some used for over a century (DoEE, 2018c) The species feed on fruit and nectar from the canopy and use a range of vegetation communities, including rainforests, open forests, closed and open woodlands, *Melaleuca* swamps, and *Banksia* woodlands (DoEE, 2018c) Records are heavily concentrated throughout the Cumberland Plain subregion, particularly in Parramatta and Penrith (OEH, 2021a)The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas Species specific measures are considered necessary This species is reliant on large mature trees and sensitive to camp disturbance, therefore specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Saccolaimus flaviventris	Yellow-bellied Sheathtail-bat	N/A	V	ECS	Disturbance to roosting and summer breeding sites Loss of hollow-bearing trees	The Yellow-bellied Sheathtail-bat is distributed across northern and eastern Australia. The species roosts in tree hollows and buildings or mammal burrows in treeless areas. Foraging for insects occurs in most habitats across its very wide range (OEH, 2017aj) Records in the Cumberland Plain subregion are primarily concentrated in Parramatta with a few in Kurrajong, Penrith, Campbelltown, and Picton (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address indirect impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						This species is reliant on large mature trees for roosting and sensitive to disturbance, therefore additional specific mitigation measures have been identified to mitigate residual risks	
Scoteanax rueppellii	Greater Broad-nosed Bat	N/A	V	ECS	Disturbance to roosting and summer breeding sites Loss of hollow-bearing trees	The Greater Broad-nosed Bat is found mainly in the gullies and river systems that drain the Great Dividing Range from north-eastern Victoria to the Atherton Tableland. In NSW, the species is widespread on the New England Tablelands. The species primarily inhabits tall wet forest but occurs in a wide range of habitats from woodland through to moist and dry eucalypt forest and rainforest. Roosting generally occurs in tree hollows but occasionally in buildings. Foraging occurs in open woodland habitat and dry open forest for direct flight (OEH, 2017p) Records are heavily dispersed across the Cumberland Plain subregion except for the south-west corner in Picton (OEH, 2021a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts This species is reliant on large mature trees for roosting and sensitive to disturbance, therefore additional specific mitigation measures have been identified to mitigate residual risks	Yes
REPTILES							
Hoplocephalus bungaroides	Broad-headed Snake	V	E	ECS	Bush rock removal Inappropriate fire regimes Predation by cats Road mortality	The Broad-headed Snake occurs in the sandstone ranges in the Sydney Basin within a 200 km radius of Sydney. The species is found in four main areas: • Blue Mountains • Southern Sydney • An area outside of the Cumberland Plain, to the north-west • The Nowra hinterland (DoE, 2014c) Adults shelter in rocky outcrops during colder seasons and move to adjacent sclerophyll woodlands in warmer seasons with a preference for sites they have	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						previously used. In woodland areas, the species is found in large trees with multiple hollows and dead trees. Pregnant females and juveniles remain in rocky habitat, using cooler, shaded rocks, and crevices (DoEE, 2018c) There is a single current record of the Broad-headed Snake within the Strategic Assessment Area, reflecting the largely unsuitable habitat across most of the area. The record is dated from 2014 located in the southern section of the Strategic Assessment Area, near Buxton The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because • There is only one current record of the species in the Strategic Assessment Area, greater densities of records occur in surrounding areas, in particular to the south-east of the subregion • The removal of bush rock in many reserves is prohibited and management plans for reserves typically include measures to control public access within reserves, which may reduce the risk of bush rock removal for the species As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. These measures are expected to manage any potential impacts to the species	
Varanus rosenbergi	Rosenberg's Monitor	N/A	V	ECS	Removal of habitat elements, such as termite mounds and fallen timber Predation by cats and dogs	The Rosenberg's Monitor is found in Wollemi National Park to the north-west of Sydney, Cooma, Goulburn, and ACT regions. The species is also found in WA and SA. Occurring in heath, open forest and woodland, the Rosenberg's Monitor is associated strongly with termites as termite mounds are a critical habitat component. The species also finds shelter in rock crevices, hollow logs and burrows (OEH, 2017y). There is one record of the Rosenberg's Monitor that occurs towards the western boundary of the Cumberland Plain subregion although the species is widely reported to the south and southeast The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC.	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • There are no records of the species within or nearby the nominated areas • Greater densities of records occur elsewhere in the bioregion • The species is considered unlikely to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. These measures are expected to manage any residual impacts to the species	
AMPHIBIANS							
Heleioporus australiacus	Giant Burrowing Frog	V	V	SCS	Hydrological changes Inappropriate fire regimes Predation by foxes and cats Vehicle strike Infection with amphibian chytrid fungus	The Giant Burrowing Frog is found in Victoria and NSW up to 100 km inland and 1,000 m above sea level. The species may comprise of two separate species, one in the north (Central Coast and Sydney Region) and one in the south (south of Kiama), although revision is still underway. The northern population is confined to areas of sandstone geology, and is found in ephemeral and semi-permanent streams, beside perennial creeks, on sandstone shelves in hanging swamps, and at times in artificial dams, ditches and culverts (DAWE, 2020c). Records of the species within the Strategic Assessment Area are limited and sporadic, the largest of which occurs in Gulguer Nature Reserve, along with individual records at Picton, Castlereagh, and Cambridge Park The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • There are limited records of the species in the Strategic Assessment Area and a lack of suitable habitat in the subregion • Greater densities of records occur in surrounding areas, in particular to the south-east of the subregion	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
						• The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, inappropriate fire regimes, predation, vehicle strike and disease. These measures are expected to manage any residual impacts to the species	
Litoria aurea	Green and Golden Bell Frog	V	E	SCS	Changes to the structure and diversity of aquatic vegetation Changes to hydrology and water quality Intensification of public access to habitat Predation cats Inappropriate fire regimes Infection with amphibian *chytrid* fungus	The Green and Golden Bell Frog is recorded throughout coastal lowland areas of Victoria and NSW from Lake Wellington (south) to Yuraygir National Park (north). The species is found in the areas around Sydney and in the Cumberland subregion. The species has been recorded sporadically throughout the Strategic Assessment Area north of Liverpool, with outlying populations near Razorback, Narellan, and Campbelltown. The Green and Golden Bell Frog occurs in still, shallow, temporary, and unshaded water bodies with terrestrial habitats of low vegetation and grassy areas. Ephemeral water bodies are important for this species for breeding, habitat connectivity, and due to the absence of mosquito fish (DEWHA, 2009) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the OSO transport corridor in GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the potential population associated with Ropes Creek corridor is on the edge of the western range for the species and could be potentially impacted by development under the Plan, species-specific commitments are required to address potential residual impacts	Yes
Pseudophryne australis	Red-crowned Toadlet	N/A	V	SCS	Changes to hydrology and pollution/	The distribution of the Red-crowned Toadlet is confined within the Sydney Basin between Pokolbin (north), Nowra (south) and Mt Victoria in the Blue Mountains. The species has been recorded within the subregion with isolated records near Pitt Town,	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
					degradation of water quality Inappropriate fire regimes Habitat degradation through four-wheel driving and trail bikes Bush rock removal	Narellan, and Picton, and is extensively recorded in the area surrounding the subregion. The species is found in open forests, and shelters under rocks or in dense vegetation or piles of leaf litter. Successful breeding is related to water quality; Red-crowned Toadlets have not been recorded in water with a pH above or below 5.5-6.5, or water that is even mildly polluted (OEH, 2019q) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion • The removal of bush rock in many reserves is prohibited and management plans for reserves typically include measures to control public access within reserves, which may reduce the risk of bush rock removal for the species As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. These measures are expected to manage potential residual impacts	
INVERTEBRATES							
Meridolum corneovirens	Cumberland Plain Land Snail	N/A	E	SCS	Weed invasion Inappropriate fire regimes Removal of fallen logs for firewood Loss of ground shelter habitat by slashing	The Cumberland Plain Land Snail occurs in the Cumberland Plain from Richmond to Picton, and from Liverpool West to the Nepean Rivers at the base of the Blue Mountains. The species has been widely recorded throughout the entirety of the Strategic Assessment Area. The Cumberland Plain Land Snail occurs mostly in Cumberland Plain Woodland, living under litter of bark, leaves and logs, around grass clumps, and occasionally rubbish (OEH, 2019f) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Relevant indirect impacts / specific threats	Assessment of indirect impacts	Residual impacts
					Ground subsidence	As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the species is restricted to the subregion, additional species-specific commitments are required to address potential residual impacts and to support critical actions for the species under the Saving our Species program	
Pommerhelix duralensis	Dural Land Snail	E	E	N/A	Inappropriate fire regimes Disturbance due to weed control activities	The Dural Land Snail is endemic to NSW and occurs mostly along the north-east fringes of the Cumberland subregion. Isolated records occur within the Strategic Assessment Area near Richmond, Silverdale, Cranebrook, St Helens Park and Londonderry. The species is found on shale-sandstone-transitional landscapes and is dependent on shale availability. The Dural Land Snail inhabits forests with woody debris and native cover, it is considered intolerant of weedy and highly disturbed habitats (DoE, 2015d) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in WSA and GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • There are no records close to urban capable land or transport corridors, or in areas most at risk of indirect impacts from development • The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and disturbance from weed control activities. These measures are expected to manage potential residual impacts	No

15.7.2 FLORA

Table 15-18: Assessment of indirect impacts – flora

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Acacia bynoeana	Bynoe's Wattle, Tiny Wattle	V	E	SCS	Inappropriate habitat disturbance Weed invasion Inappropriate fire regimes	The Bynoe's Wattle is widely distributed throughout central-eastern NSW including the Cumberland IBRA subregion (OEH, 2019c). Occurrences have been widely reported in the Strategic Assessment Area near Londonderry, with outlying occurrences reported near Liverpool and Wilton. The species is recorded in open and at times slightly disturbed sites, and inhabits heath or dry sclerophyll forests on sandy soils (OEH, 2017d) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC and Wilton. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of records occur away from urban capable land and transport corridors • The majority of mapped potential habitat is of low habitat value or is of limited extent within GMAC and Wilton (Douglas, 2019) • Some habitat for the species is subject to approval conditions to protect and manage it from indirect impacts, under an existing EPBC Act approval in the Bingara area. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. These measures are expected to manage potential residual impacts	No
Acacia pubescens	Downy Wattle, Hairy Stemmed Wattle	V	V	SCS	Weed invasion Habitat disturbance through illegal track creation and maintenance activities Inappropriate fire regimes	The Downy Wattle distribution is limited to the Sydney district, and is found predominantly in the Cumberland subregion (NSW NPWS, 2003). Occurrences of the species have been widely reported within the Strategic Assessment Area in the areas surrounding Liverpool and Pitt Town. The species occurs on shales, alluviums and at the intergrade between shales and sandstones. The species is typically found in open woodland and forest, throughout a variety of plant communities (DoEE, 2018c). Recruitment primarily occurs through vegetative reproduction (NSW NPWS, 2003) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in the nominated areas	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
						and transport corridors outside the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of records occur away from urban capable land and transport corridors • The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion, disturbance and inappropriate fire regimes. These measures are expected to manage potential residual impacts	
Allocasuarina glareicola		E	E	SCS	Habitat degradation from increased public access Inappropriate fire regimes Weed invasion	*Allocasuarina glareicola* is distributed within the Cumberland subregion, primarily the Castlereagh and Londonderry areas with a total extent of occurrence (EOO) of 27 km^2. The species is found in open woodland and Castlereagh woodland on soil characterised by strong acidity and low fertility. As the species is wind pollinated, the distance between populations may be a critical factor for seed set and pollination (DoEE, 2018c; OEH, 2018b) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of records and potential habitat occur away from urban capable land and transport corridors • Several areas of potential habitat and records are managed in existing conservation reserves As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including habitat degradation, inappropriate fire regimes and weed invasion. These measures are expected to manage potential residual impacts	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Commersonia prostrata	Dwarf Kerrawang	E	E	N/A	None	The distribution of the Dwarf Kerrawang ranges from central Gippsland (Victoria) to the NSW coast. It is known to occur in the Cumberland region, and is found near Tallong, Goulburn, Penrose, and Newcastle (DoEE, 2018a; OEH, 2017h, 2020a). Occurrence of the species in the Strategic Assessment Area has been recorded in Thirlmere Lakes National Park near Couridjah. The species is endemic to South-eastern Australia. The Dwarf Kerrawang is typically found on peaty or sandy soils in a range of habitats including but not limited to Brittle Gum Low Open Woodland at Penrose, and Snow Gum Woodland at Rose Lagoon (DoEE, 2018a; OEH, 2017h, 2020a) While the Plan has the potential to exacerbate some threats to the species, this is unlikely to result in indirect impacts to the species because the majority of areas of habitat occur some distance away from the urban capable land and transport corridors and away from associated areas that could be impacted	N/A
Cynanchum elegans	White-flowered Wax Plant	E	E	N/A	Degradation of habitat due to weed invasion, grazing and inappropriate fire management Hydrological disturbance	The distribution of the White-flowered Wax Plant ranges from Brunswick heads to the Illawarra region in Eastern NSW (DEWHA, 2008a). Occurrences of the species within the Strategic Assessment Area have been reported sporadically near Razorback, Oran Park, and Grose Vale. The species distribution overlaps with various TEC's including but not limited to Cumberland Plain Woodlands and Shale Sandstone Transition Forest. The species typically resides in the transition zone between sclerophyll forest/woodland and subtropical rainforest on steep slopes (DEWHA, 2008a) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the OSO transport corridor near Cobbitty, south of WSA As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because an important population occurs close to the OSO transport corridor, additional species-specific commitments are required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Deyeuxia appressa		E	E	N/A	None	Recorded observances of the species are limited to the Sydney region, although the species may be extinct with the last observation prior to 1942. There are no current recorded occurrences of the species within the Strategic Assessment Area. Understanding of the species is limited. The species is known to grow in moist conditions in three TECs; Shale and Sandstone Transition Forest, Cumberland Plain Woodlands, and Turpentine-Ironbark Forest in the Sydney Basin Bioregion (DEWHA, 2008b; OEH, 2018e) While the Plan has the potential to exacerbate some threats to the species, this is unlikely to result in indirect impacts to the species because all three records of the species (if extant) and potential habitat occur outside the Strategic Assessment Area and some distance from the urban capable land and transport corridors and transport corridors and away from associated areas that could be impacted	N/A
Dillwynia tenuifolia		N/A	V	SCS	Inappropriate fire regimes Disturbance from human activity such as rubbish dumping and uncontrolled vehicular access Weed invasion	The core distribution of the species is within the Cumberland Plain, ranging from Windsor and Penrith to Dean Park. The species is also found in the Bulga Mountains, Kurrajong Heights, and Woodford in the Blue Mountains. Occurrences of *Dillwynia tenuifolia* in the Strategic Assessment Area have been recorded extensively in the areas surrounding Londonderry and Kemps Creek. The species may be locally abundant in scrubby/dry heath areas in Castlereagh Ironbark Forest and Shale Gravel Transition Forest in Western Sydney (OEH, 2017f) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in WSA and GPEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion, disturbance, and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for the species and records and potential habitat occurs close to urban capable land and transport corridors. Additional species-specific commitments are therefore required to strengthen protection and address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Epacris purpurascens var. *purpurascens*		N/A	V	SCS	Urban run-off Inappropriate fire regimes Disturbance from human activity such as rubbish dumping, trampling and uncontrolled vehicular access Weed invasion	The species is distributed in NSW between Gosford (north), Narrabeen (east), Silverdale (West) and Avon Dam (South). Occurrences of the species within the Strategic Assessment Area have been recorded primarily in the area around Wilton. The species is found in a range of habitats characterised by the presence of shale soil (OEH, 2017k) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. These measures are expected to manage potential residual impacts	No
Eucalyptus benthamii	Camden White Gum, Nepean River Gum	V	V	SCS	Inappropriate fire regimes Changed hydrology Weed invasion Myrtle rust Ground subsidence	The Camden White Gum is found in the Cumberland subregion and the Blue Mountains. Occurrences of the species within the Strategic Assessment Area have been recorded sporadically with most records in the areas surrounding The Oaks and Camden. The distribution of the species overlaps with EPBC Act-listed TECs including the Cumberland Plain Shale Woodlands and Shale Gravel Transition Forest, and the Shale Sandstone Transition Forest. The species is typically found in fertile, alluvial sands in areas with a flooding regime to allow the establishment of seedlings (DoE, 2014b) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to GPEC, GMAC and the OSO transport corridor As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species,	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
						including inappropriate fire regimes, impacts to hydrological processes, weed invasion and spread of disease These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the species has been identified as being at risk from indirect impacts from the OSO tunnel, and additional specific measures are required to address potential residual impacts in relation to this	
Genoplesium baueri	Yellow Gnat-orchid	E	E	N/A	Habitat disturbance from recreational use, rubbish dumping, and nearby urban areas	The Yellow Gnat-orchid, an endemic species to NSW, is distributed in coastal regions primarily between Ulladulla and Port Stephens. The species has also been observed outside this range in the Blue Mountains and Penrose State Forest. Records of occurrence within the Strategic Assessment Area are limited, with singular observations near Campbelltown, Appin, and Bargo. The species typically grows in either shrubby forest to heathy forest on well drained sandy and gravelly soils, or heathland to shrubby woodland on sand or sandy loams (DoE, 2014e). The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC There are very few records of this species in the subregion, however, a population (no. 21) occurs close to the urban capable land in GMAC and an additional species-specific commitment is required to address potential residual impacts in this location	Yes
Grevillea juniperina subsp. *juniperina*	Juniper-leaved Grevillea	N/A	V	SCS	Inappropriate fire regimes Disturbance from human activity such as rubbish dumping, trampling and increased fire risk Weed invasion	The Juniper-leaved Grevillia is endemic to Western Sydney, with records primarily occurring in the area between Blacktown, Erskine Park, Londonderry and Windsor, and outlying records of occurrence in Kemps Creek and Pitt Town. The species is known to occur in Cumberland Plain Woodland, Castlereagh Ironbark Woodland, Castlereagh Scribbly Gum Woodland and Shale/Gravel Transition Forest (OEH, 2019h) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in WSA and GPEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
						the species, records and potential habitat occur close to urban capable land and transport corridors, so additional species-specific commitments are required to address potential residual impacts	
Grevillea parviflora subsp. *parviflora*	Small-flower Grevillea	V	V	SCS	Road maintenance Weed invasion Habitat disturbance from recreational activities and rubbish dumping Inappropriate fire regimes	The Small-flower Grevillea is endemic to NSW and occurs in a range of areas including Picton, Appin, Bargo, Holsworthy, the Lower Hunter Valley, the Central Coast and Port Stephens. The species is recorded sporadically throughout the Strategic Assessment Area, primarily near Holsworthy, Wilton, Bargo, and Kemps Creek. The species is typically found growing on sandy to gravelly clay soils on upper slopes, crests, or flat plains. Distribution of the Small-flower Grevillea overlaps with numerous TECs including the Cumberland Plain Woodlands, Shale Sandstone Transition Forest, Turpentine-Ironbark Forest, Castlereagh Scribbly Gum and Agnes Banks Woodland, and Cooks River/Castlereagh Ironbark Forest (DEWHA, 2008c) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in Wilton As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. In addition, some habitat for the species is subject to approval conditions to protect and manage it from indirect impacts, under an existing EPBC Act referral (EPBC 2014/7400) in the Bingara area These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because an important population occurs close to the urban capable land in Wilton, additional species-specific commitments are required to address potential residual impacts in that location	Yes
Hibbertia fumana		N/A	CE	SCS	Inappropriate fire regimes Weed invasion Habitat disturbance from uncontrolled	The distribution of the species ranges across greater Sydney from Richmond to Mittagong. Occurrences of *Hibbertia fumana* have been recorded in the Strategic Assessment Area near Holsworthy. The species has been known to occur primarily in the intergrade between Castlereagh Scribbly Gum Woodland and Castlereagh Ironbark Forest, in a variety of structural habitats including disturbed sites, open areas, and within thick ground cover (OEH, 2020d)	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					movement of vehicles	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC, around the Kemps Creek area in WSA and in Wianamatta Regional Park in GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • A large number of records occur in protected areas in Moorebank to the north of GMAC, which is a proposed priority management site under the NSW Saving our Species strategy As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, weed invasion and disturbance. These measures are expected to manage potential residual impacts	
Hibbertia puberula		N/A	E	SCS	Weed invasion Disturbance from human activity such as from trailbikes, 4WDs and mountain bikes	The species is distributed widely throughout NSW from Wollemi National Park to Morton National Park. *Hibbertia puberula* has been recorded within the Strategic Assessment Area primarily near Holsworthy, with more sporadic records between Holsworthy and Campbelltown. The species is often found on sandy soils, in dry sclerophyll woodland communities and more rarely heaths (OEH, 2017r) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC, in particular the northern boundary adjacent to Shanes Park. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • A large number of records occur in protected areas in Moorebank to the north of GMAC, which is a proposed priority management site under the NSW Saving our Species strategy	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
						• The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and disturbance. These measures are expected to manage potential residual impacts	
Leucopogon exolasius	Woronora Beard-heath	V	V	N/A	Inappropriate fire regimes Weed invasion	The Woronora Beard-heath is endemic to the Sydney and Central Coast regions of NSW. The distribution of the species is fragmented, although it is known to occur in the Cumberland IBRA subregion. Occurrences within the Strategic Assessment Area have been recorded near Campbelltown, with isolated records near Appin, Moorebank and Richmond. The species is found on sandstone and sandy alluvium areas in woodlands, and also occurs on rocky hillsides and along creek banks (DoEE, 2018c; OEH, 2017ah) The Plan has the potential to exacerbate some threats in areas of habitat for this species that occur adjacent to GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion • The populations nearest to the nominated area have been classified as non-important populations As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. These measures are expected to manage potential residual impacts	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Marsdenia viridiflora subsp. *viridiflora*		N/A	E	SCS	Stochastic events (e.g. fire) due to small population size	The species is distributed throughout NSW with known populations in Prospect, Bankstown, Smithfield, Cabramatta Creek and St Marys. Occurrences within the Strategic Assessment Area are scattered between Londonderry and Narellan. The species is known to grow in vine thickets and open shale woodland (OEH, 2019k) The Plan has the potential to exacerbate some threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC, WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including undertaking bushfire reduction measures close to the urban capable land, which is likely to reduce the likelihood of stochastic events such as wildfires affecting the species	No
Maundia triglochinoides		N/A	V	SCS	Hydrological changes Weed invasion	The distribution of *Maundia triglochinoides* is restricted to coastal NSW and southern Queensland. The Southern limit for the species is Wyong, as former sites surrounding Sydney have become extinct. There are no recorded occurrences within the Strategic Assessment Area. The species is known to grow in lagoons, dams, swamps, creeks, channels or shallow freshwater (OEH, 2019m) The Plan has the potential to exacerbate some threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC and WSA As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes and weed invasion	No
Melaleuca deanei	Deane's Melaleuca	V	V	SCS	Inappropriate fire regimes and mechanical	The species is known to occur in the Cumberland IBRA subregion, although records primarily occur in the Ku-ring-gai/Berowra and Holsworthy/Wedderburn areas (OEH, 2019g). Occurrences of the species have been recorded within the Strategic Assessment Area near Wilton and Kentlyn. The species is found on sandstone and sandy soils in ridgetop woodland and wet heath (DoEE, 2018c; OEH, 2019g). Over 50 per cent of	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					methods of bushfire removal Inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access, and rubbish dumping Weed invasion	Deane's Melaleuca populations are currently protected in national parks or nature reserves (NSW DECCW, 2010) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. However, because the species is sensitive to inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access and rubbish dumping, an additional species-specific commitment is required to address potential residual impacts in relation to these issues	
Micromyrtus minutiflora		V	E	SCS	Inappropriate fire regimes Weed invasion Habitat degradation through arson, grazing, trail bike riding, and rubbish dumping	*Micromyrtus minutiflora* is endemic to the Western region of the Cumberland Plain. Occurrence of the species within the Strategic Assessment Area is recorded primarily in the area surrounding Londonderry. The distribution of the species overlaps with the following TECs, Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest, Cooks River/Castlereagh Ironbark Forest, and Castlereagh Scribbly Gum and Agnes Banks Woodlands. The species grows in open forests on consolidated river sediments and tertiary alluvium (DEWHA, 2008d; OEH, 2019n) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion • Many records occur in existing conservation reserves in the north of the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and intensive plant agriculture	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
						development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, weed invasion and disturbance. These measures are expected to manage potential residual impacts	
Persicaria elatior	Tall Knotweed	V	V	SCS	Hydrological changes Inappropriate habitat disturbance, such as through road, track and trail maintenance Weed invasion	The Tall Knotweed is distributed throughout the coastal regions of south-eastern Australia, occurring in the North Coast, Central Coast and South Coast botanical subdivisions. The species has primarily been recorded along coastal regions, although one occurrence has been recorded in the Cumberland IBRA subregion near Picton. The species grows on sandy, alluvial soil in damp places including watercourses, lakes, streams, in swamp forests, in coastal swampy areas and disturbed areas. The distribution of the species overlaps with the Coastal Swamp Oak (*Casuarina glauca*) Forest TEC (DEWHA, 2008e; DoEE, 2018c) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to GMAC, WSA, GPEC and transport corridors. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion are protected in an existing conservation reserve some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, disturbance and weed invasion. These measures are expected to manage potential residual impacts	No
Persoonia bargoensis	Bargo Geebung	V	E	SCS	Inappropriate fire regimes and fire maintenance activities	The distribution of Bargo Geebung is restricted to an area of south-west Sydney on the western edge of the Woronora Plateau and northern edge of the Southern Highlands. The species is also known to occur in the Cumberland, Burragorang, and Sydney Cataract regions (OEH, 2019a). Occurrence within the Strategic Assessment Area has	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					Inappropriate habitat disturbance Infection by *Phytophthora cinnamomi*	been widely recorded in the areas surrounding Wilton and Bargo. The species is found in dry sclerophyll eucalypt woodland or forest (DoEE, 2018c) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. In addition, some habitat for the species is subject to approval conditions to protect and manage it from indirect impacts, under an existing EPBC Act referral (EPBC 2014/7400) in the Bingara area These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, there is potential for some residual risks to the species relating to inappropriate fire regimes, disturbance from habitat maintenance and P*hytophthora cinnamomic*. Additional species-specific commitments are required to address these issues	
Persoonia glaucescens	Mittagong Geebung	V	E	N/A	None	The Mittagong Geebung has a restricted distribution in NSW from the Kangaroo Valley to Picton and is known to occur in the Cumberland IBRA subregion (OEH, 2019c). Several occurrences of the species have been recorded in the Strategic Assessment Area near Bargo and Buxton. The distribution of the species overlaps with various TECs including Shale Sandstone Transition Forest, White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland, Turpentine Iron-bark Forest, and Temperate Highland Peat Swamps. The species prefers ridge-tops and upper slopes in woodland to dry sclerophyll forest (DEWHA, 2008f; OEH, 2017v, 2019o) While the Plan has the potential to exacerbate some threats to the species, this is unlikely to result in indirect impacts to the species because the records and majority of areas of habitat occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A
Persoonia hirsuta	Hairy Geebung, Hairy Persoonia	E	E	N/A	Inappropriate fire regimes	The Hairy Geebung has a scattered distribution around the Sydney region and is known to occur in the Cumberland IBRA subregion. A number of occurrences of the species have been recorded in the Strategic Assessment Area including near to Tahmoor, Bargo,	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					Disturbance from recreational users Altered hydrology Weed invasion Infection by *Phytophthora cinnamomi*	and Castlereagh. The species is found in dry sclerophyll open forest and woodland on sandy to stony soils (DoE, 2014d; OEH, 2017q) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to all nominated areas and the OSO transport corridor As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, altered hydrology and weed invasion. In addition, all known populations are on privately owned land which reduces the risk of disturbance from recreational users These measures are expected to address potential indirect impacts from development under the Plan on this species, and are expected to manage potential residual impacts	
Persoonia nutans	Nodding Geebung	E	E	SCS	Inappropriate fire regimes Habitat degradation and rubbish dumping related to unrestricted access Infection by root-rot fungus *Phytophthora cinnamomi* Weed invasion	The distribution of the Nodding Geebung is restricted to the Cumberland region, primarily near the Nepean and Georges River between Richmond and Macquarie Fields. The species is considered to occur predominantly in the Penrith area, although occurrences have been recorded within the Strategic Assessment Area near Kemps Creek, Moorebank, and Castlereagh. The species depends on aeolian and alluvial sediments, and is found in the Agnes Banks and Berkshire Park soil landscapes on low rises (DoEE, 2018c; NSW DEC, 2005) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because an important population and potential habitat occur close to the OSO transport corridor within Wianamatta Regional Park in GPEC, additional specific measures are required to address potential residual impacts in that area	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Pimelea curviflora var. *curviflora*		V	V	SCS	Weed invasion Habitat degradation from recreational activities, road and trail maintenance, and bush rock removal Inappropriate fire regimes	The *Pimelea curviflora* is found in the coastal regions of Sydney and Illawarra in NSW. As of 1998, the species has been known to occur in 20 locations between Maroota and northern Sydney. A further population was identified in Shellharbour in 2011. The species has been recorded in the Strategic Assessment Area near Wilton, Windsor Downs, and Agnes Banks. The distribution of the species overlaps with various TECs including Shale Sandstone Transition Forest, Blue Gum High Forest of the Sydney Basin Bioregion, Cumberland Plain Woodlands, and Turpentine-Ironbark Forest in the Sydney Basin Bioregion. The species is found in open forest and woodland on sandy soil, shaly soil or shale/transition soil (DEWHA, 2008g; DoEE, 2018c) The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in GMAC, Wilton and GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species occurs elsewhere in the bioregion • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion • Many records are protected in existing conservation reserves As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, disturbance and weed invasion. These measures are expected to manage potential residual impacts	No
Pimelea spicata	Spiked Rice-flower	E	E	SCS	Illegal dumping of rubbish and garden waste Weed invasion and competition	The species occurs throughout NSW in the Sydney Basin, the Cumberland Plain, and Illawarra region. The distribution of the species in the Cumberland Plain is known to range from the Marayong and Prospect Reservoir south to Narellan Vale and Douglas Park. The species has been recorded sporadically throughout the entirety of the Strategic Assessment Area. The habitat for the species is associated with the Cumberland Plain	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					High frequency land-use/management activities Inappropriate fire regimes Hydrological disturbance Ground subsidence	Shale Woodlands and Shale Gravel Transition Forest, along with Western Sydney Dry Rainforest and Moist Woodland on Shale Woodland (DEC, 2005; TSSC, 2016b) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in all nominated areas and transport corridors outside the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, residual risks associated with human disturbance and indirect impacts from the OSO tunnel have been identified, so additional specific measures are required to address these issues	
Pomaderris brunnea	Rufous Pomaderris	V	E	SCS	Weed invasion Disturbance from trampling and recreational vehicle use Stormwater run-off Altered fire regimes Ground subsidence	The Rufous Pomaderris is endemic to south-eastern Australia occurring in eastern NSW, the North Coast of NSW, the New England bioregion, and eastern Victoria. The Strategic Assessment Area is considered a core location for the species, with numerous occurrences reported south of Gregory Hills. The species inhabits alluvial soils on flood plains and creek lines, and clay in moist woodlands or forests (Sutter, 2011) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC and Wilton and transport corridors outside the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the species has been identified as being at risk from indirect impacts from the OSO tunnel, and additional specific measures are required to address potential residual impacts associated with this	Yes
Pterostylis saxicola	Sydney Plains Greenhood	E	E	SCS	Weed invasion	The distribution of the Sydney Plains Greenhood orchid is restricted to Western Sydney between Picton in the south and Freemans Reach in the north (DEWHA, 2008h; DoEE,	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					Inappropriate fire regimes Inappropriate habitat disturbance Unrestricted access	2018c). The species has been recorded sporadically throughout the Strategic Assessment Area. On the Cumberland Plain, the species occurs along an ecological gradient from clay soils on gently hilly landscapes (PCT 849), to clay to sandy soils (PCT 1395), to thin accumulations of humus-rich sandy soil on sandstone rock shelves (PCTs 1081, 1083, 1181 and 1789) (Weston, 2018) The Plan has the potential to exacerbate potential impacts in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC, GMAC and Wilton Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because the species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. However, the species has been identified as being at risk from indirect impacts associated with habitat disturbance, and additional specific measures are required to address potential residual impacts	
Pultenaea parviflora		V	E	SCS	Inappropriate habitat disturbance from uncontrolled vehicle access and rubbish dumping Inappropriate fire regimes Weed invasion	The distribution of *Pultenaea parviflora* is restricted to the Cumberland Plain, primarily between Penrith and Windsor. Further outlying occurrences of the species have been recorded in the Strategic Assessment Area near Kemps Creek and Wilberforce. The species grows in sclerophyll woodlands, forests or in derived grasslands (DoEE, 2018c; OEH, 2017x) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC and WSA As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
						the species, and records and potential habitat occur close to urban capable land and transport corridors. Additional species-specific commitments are therefore required to address potential residual impacts	
Pultenaea pedunculata	Matted Bush-pea	N/A	E	SCS	Inappropriate fire regimes Disturbance from human activity Weed invasion	The Matted Bush-pea is widespread in south-eastern Australia, Tasmania, and Victoria. In NSW there are three disjunct populations, located on the Cumberland Plain, the coast of NSW between Bermagui and Tathra, and in Windellama. The species has been recorded within the Strategic Assessment Area near Liverpool, Narellan, and Appin. In NSW, the species is typically found in woodland vegetation and sometimes road batters and coastal cliffs (OEH, 2018g) The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for the species, records and potential habitat occur close to urban capable land in GMAC. Additional species-specific commitments are required to address potential residual impacts	Yes

15.7.3 THREATENED ECOLOGICAL COMMUNITIES

Table 15-19: Assessment of indirect impacts – TECs

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	*Castlereagh Scribbly Gum Woodland in the Sydney Basin Bioregion*	E	V	Inappropriate fire regimes Weed invasion Invasive fauna Diseases, pathogens, and dieback Damage caused by human disturbance	The distribution of the TEC is restricted to the Sydney Basin bioregion, occurring across the Cumberland subregion and the margin of the Sydney Cataract, Wollemi and Burragorang subregions. The TEC is found within the Strategic Assessment Area in larger patches in the Castlereagh area, with other occurrences in Holsworthy, Tahmoor, Kemps Creek and Longneck Lagoon. The TEC typically grows on Tertiary sands and gravels of the Hawkesbury-Nepean river system, at elevations below 80 m with mean annual rainfall of 700-900 mm (DoE, 2015b) While areas of mapped TEC occur some distance from the urban capable land and transport corridors, the Plan has the potential to exacerbate several threats to the TEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC. These measures are expected to manage any residual impacts to the TEC	No
River-flat Eucalypt Forest on Coastal Floodplains of Southern New South Wales and Eastern Victoria	*River-flat Eucalypt Forest on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions*	CE	E	Inappropriate fire regimes Weed invasion Changes to hydrology Invasive fauna Diseases, pathogens, and dieback Damage caused by human disturbance Urban heat island effect Ground subsidence	The TEC extends through two IBRA Bioregions, Sydney Basin and South-East Corner, and is distributed from Sale in Victoria to the north of Newcastle in NSW. The community is typically found in riparian corridors, floodplains, older floodplain terraces, and floodplain depressions at elevations below 50m. The TEC often forms mosaics with wetland and floodplain forest communities, and is important for riverbank stability and river ecosystems (DAWE, 2020b) The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to the urban capable land in the nominated areas and in the transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial	Yes

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	*Swamp Oak Floodplain Forest of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions*	E	E	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens, and dieback Invasive fauna	The TEC is widely distributed along the east coast of Australia from Bermagui in NSW to Curtis Island in Queensland. The occupancy of the community within the Strategic Assessment Area is limited within Cranebrook to Bow Bowing. The TEC occurs is coastal catchments within 30 km of the coast on unconsolidated sediments at elevations below 50 m (DoEE, 2018b) The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to the urban capable land and transport corridors in WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	Yes
Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion	*Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	CE	E	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance	The TEC is confined to the Sydney Basin and distribution is primarily restricted to the Cumberland subregion. The community is found in larger patches in the Castlereagh, Kemps Creek and Holsworthy areas, with smaller patches in the eastern part of the subregion. The TEC is found in areas with an annual rainfall of 800-1000 mm at	Yes

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
				Changes to hydrology Diseases, pathogens, and dieback Invasive fauna	elevation below 100m, generally growing on clay soils or Wianamatta Shale soils (DoE, 2015c) The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to urban capable land and transport corridors in WSA and GPEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks. In addition, there is a TEC-specific commitment to undertake all control measures in line with the *Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest* and *Recovering Bushland on the Cumberland Plain: best practice guidelines on the management and restoration of bushland*	
	Cumberland Plain Woodland in the Sydney Basin Bioregion		CE	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens, and dieback Invasive fauna Ground subsidence	The TEC occurs throughout drier regions of the Sydney Basin and was previously extensive across the Cumberland Plain. Currently, 9% of original extent remains, with remnants scattered throughout the Cumberland subregion. Larger patches have been recorded in the northern area of the Strategic Assessment Area in GPEC and near Pitt Town. The community occurs on heavy soils derived from Wianamatta Shale (OEH, 2009) The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to the urban capable land in the nominated areas and transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental	Yes

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	
	Shale Gravel Transition Forest in the Sydney Basin Bioregion		E	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens, and dieback Invasive fauna	The TEC is distributed primarily in the northern region of the Cumberland Plain. The community is recorded within the northern section of the Strategic Assessment Area near Pitt Town, Marsden Park and Richmond, with outlier areas at Kemps Creek and Liverpool. The TEC is a transitional plant community, and grades into Cumberland Plain Woodland, Cooks River/Castlereagh Ironbark Forest, or Castlereagh Scribbly Gum Woodland (OEH, 2020g) The Plan has the potential to exacerbate threats in areas of this TEC that occur adjacent to the urban capable land and transport corridors in WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	Yes
Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion	*Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion*	CE	CE	Changes to hydrology	The TEC occurs only in the Sydney Basin bioregion within the Cumberland subregion. It is recorded in the Camden LGA, where small patches occur in cleared and mined tertiary sand deposit. The community occurs in areas with mean annual rainfall of approximately 750mm at elevations of 60-100m (DAWE, 2020a)	No

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
					The Plan has the potential to exacerbate threats in areas associated with the OSO and Metro Rail Future Extension tunnels. As described in section 15.6, mitigation measures will be implemented through future environmental assessment processes (for transport development) that will address potential indirect impacts from hydrological disturbance in the vicinity of the tunnel footprints. These measures are expected to manage any residual impacts to the TEC	
	Freshwater Wetlands on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions		E	Hydrological disturbance Weed invasion Inappropriate habitat disturbance	The TEC occurs throughout the majority of the NSW coast although it is distinct from Sydney Freshwater Wetlands associated with sandplains in the Sydney Basin bioregion. The community has been extensively cleared and modified, and is found within the northern region of the Strategic Assessment Area and within GPEC near Penrith (OEH, 2020c) The Plan has the potential to exacerbate threats in areas of this TEC that occur in GPEC. However, there is limited TEC mapped in the subregion and it occurs away from urban capable land and transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC. These measures are expected to manage any residual impacts to the TEC	No
Shale Sandstone Transition Forest of the Sydney Basin Bioregion	*Shale Sandstone Transition Forest in the Sydney Basin Bioregion*	CE	CE	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens, and dieback	The TEC is distributed on the edge of the Cumberland subregion, and the adjacent areas of Hornsby, Woronora, and the Lower Blue Mountains Plateaux within the Sydney Basin bioregion. The community occurs in soils derived from shale substrates and is strongly associated with the Mittagong formation. The TEC is found in areas with a mean annual rainfall of 800-1100 mm at elevations below 200m (DoE, 2014a)	Yes

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
				Invasive fauna	The Plan has the potential to exacerbate threats in areas of this TEC that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	
	Moist Shale Woodland in the Sydney Basin Bioregion		E	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changed to hydrology Diseases, pathogens, and dieback Invasive fauna	The TEC occurs primarily in the southern half of the Cumberland Plain, particularly in the Wollondilly LGA. Records of the community within the Strategic Assessment Area are concentrated near Razorback, with outlier occurrences near Campbelltown, Oran Park, Kemps Creek and Kurrajong in the north. The TEC occurs in areas at higher elevations with increased rainfall, on soils derived from Wianamatta Shale (OEH, 2020f) The Plan has the potential to exacerbate threats in areas of this TEC that occur adjacent to the urban capable land in Wilton, GMAC, and the transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial, and intensive plant agriculture development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC. These measures are expected to manage any residual impacts to the TEC	No

15.8 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

This section identifies additional specific mitigation measures considered necessary to address residual risks from the potential indirect impacts of the urban, industrial, infrastructure, intensive plant agriculture and transport development on Commonwealth and NSW-listed TECs and species, and other EPBC Act protected matters.

These mitigation measures are provided in Appendix E of the Plan and are incorporated into several commitments and actions under the Plan. The measures will be implemented as described above in section 15.6 through either:

- The draft DCP template
- A future environmental impact assessment process (for infrastructure and transport development)
- An action under the Plan

These additional mitigation measures, along with the package of relevant commitments in the Plan (see section 15.6) are considered to adequately address residual risks to each of these matters.

15.8.1 FAUNA

The specific mitigation measures to address residual risks to fauna are provided in Table 15-20.

Table 15-20: Specific mitigation measures to address residual risks – fauna

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
HABITAT FEATURES AND CONNECTIVITY						
Urban and industrial, infrastructure, intensive plant agriculture	Retain large trees (including dead trees but excluding noxious weeds) (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction	Large trees within urban landscapes are likely to be important for the persistence of several species within the subregion. Microbats benefit directly through roosting opportunities and indirectly through foraging opportunities. Flying-foxes and nectivorous birds benefit directly through foraging opportunities (high volumes of nectar). Owls and raptors benefit indirectly through large trees providing habitat for prey species	**Microbats:** Southern Myotis, Little Bent-winged Bat, Eastern Coastal Free-tailed Bat, Yellow-bellied Sheathtail-bat, Eastern False Pipistrelle, Greater Broad-nosed Bat **Flying-foxes and nectivorous birds:** Grey-headed Flying-fox, Regent Honeyeater, Swift Parrot, Little Lorikeet, and Black-chinned Honeyeater **Owls and raptors:** Barking Owl, Powerful Owl, Masked Owl, Little Eagle, White-bellied Sea Eagle, Square-tailed Kite, Spotted Harrier	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
Urban and industrial, infrastructure, intensive plant agriculture	Retain areas of high density Proteaceae shrubs where possible, particularly along riparian corridors	Proteaceae shrubs such as banksias are a favoured foraging resource for the species and the species is likely to use riparian corridors as habitat or for movement between other areas of suitable habitat	Eastern Pygmy-possum	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure
Urban and industrial, infrastructure, intensive plant agriculture	Undertake pre-construction surveys prior to removal or disturbance (seasonally dependent, before torpor) to human made structures to ensure any roosting habitat for microbat species including mine shafts, storm water tunnels, old or derelict buildings, bridges and culverts are retained where possible	Minimises the potential impacts of urban development to human-made structures that may be used by microbats for roosting or breeding	Eastern Coastal Free-tailed Bat Little Bent-wing Bat Large Bent-winged Bat Southern Myotis Yellow-Bellied Sheathtail-Bat	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure
Transport corridors	Incorporate artificial breeding and roosting habitat (e.g. bat boxes, structural cavities) in the design of bridges associated with the transport corridors in accordance with relevant guidelines or standards	Minimises the potential impacts of the transport corridors to human-made structures that may be used by microbats for roosting or breeding	Eastern Coastal Free-tailed bat Large Bent-winged Bat Southern Myotis Yellow-Bellied Sheathtail-bat	All transport corridors within and outside nominated areas	Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat	EIA process for transport

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
Urban and industrial	Design of subdivision layout including perimeter roads, Asset Protection Zones are to reduce impacts to and protect areas of koala habitat	Minimise the potential impacts of precinct operation to koala habitat	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	DCP template Mitigation Measures Guideline
Urban and industrial	Do not plant koala feed trees, as listed in Koala SEPP Schedule 2 Koala use tree species in open space and recreation areas	Koala feed trees and/or Endangered Ecological Communities are contained to open space and recreational areas in precinct design in certified urban-capable land	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with	DCP template Mitigation Measures Guideline

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
					Appendix E of the Plan	
PEST/DOMESTIC ANIMALS						
Urban and industrial, infrastructure, intensive plant agriculture	Modify pest control techniques implemented during construction and operation of the development and under the pest control strategy to reduce the risk of secondary poisoning (e.g. from Pindone or second-generation rodenticides)	There is a risk of pest control measures causing secondary poisoning of raptors	White-bellied Sea-Eagle Little Eagle Square-tailed kite Spotted Harrier	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure
				SCAs	Commitment 17: Manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the strategic conservation area	Pest control strategy
Urban and industrial, infrastructure	Where permitted and appropriate, contain domestic cats and dogs in new residential areas during operation of the development at the urban/bushland interface consistent with relevant Council guidelines	Increased numbers of domestic cats and dogs associated with urban development increases the threat of predation to native animals	Eastern Pygmy-possum Spotted-tailed Quoll	Wilton GMAC	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities	DCP
Urban and Industrial	Dog proof fenced areas are to be designated within open space and public recreation areas	Dog proof fencing provides protection to fauna including koala upfront in precinct design for public spaces	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial,	DCP template Mitigation Measures Guideline

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
					infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	
Urban and Industrial	Dog proof fencing is a design requirement for each residential lot in accordance with Council requirements	Dog proof fencing provided protection to fauna including koala upfront in precinct design for residential areas	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	DCP template Mitigation Measures Guideline

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
HUMAN DISTURBANCE						
Urban and industrial, infrastructure, intensive plant agriculture	Grey-headed flying fox camps require an 100m setback to any development. The setback area should be maintained free of flying fox roosting habitat	Minimises disturbance to known populations	Grey-headed Flying-fox	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP
Urban and industrial, infrastructure, intensive plant agriculture	Raptor nests require a 500m circular setback from where nests are located in undisturbed bushland or 250m for nests adjacent to existing development. Owl nests require a 100 m circular setback from where nests are located	Minimises disturbance to known populations	Little Eagle, White-bellied Sea Eagle, Square-tailed Kite, Spotted Harrier, Barking Owl, Powerful Owl, Masked Owl	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP
Urban and industrial, infrastructure, intensive plant agriculture	• Work with NSW Fisheries to address the risk of illegal and incidental recreational fishing capture along stretches of known habitat for Macquarie Perch in Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River • Consult with relevant resource managers about installing signs/interpretive	Minimises the risk of increased recreational fishing affecting the species due to larger urban populations associated with urban development	Macquarie Perch	Erskine Creek Glenbrook Creek Georges River Cordeaux River	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	N/A

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
	displays at appropriate sites used to access fishing locations at Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River to assist with identification and awareness of threats					
Urban and Industrial Infrastructure (including essential infrastructure)	Site assessment and pre-clearance survey to be undertaken prior to removal of vegetation to undertake koala survey and implement translocation plan if required	At pre-construction phase of development, a translocation plan and koala survey is to protect any koala on site	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	DCP template Mitigation Measures Guideline CPCP Guidelines for Infrastructure Development
Urban and Industrial Infrastructure (including essential infrastructure)	Temporary protective fencing to be erected around areas identified for conservation on or immediately adjoining the site at pre-construction phase to ensure adequate protection is in place during construction	Prior to development, at the pre-construction phase, temporary protective fencing is to be erected to protect koala entering the construction site	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney	DCP template Mitigation Measures Guideline CPCP Guidelines for Infrastructure Development

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
					koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	
Infrastructure (including essential infrastructure)	Where planned linear infrastructure such as gas and electricity transmission crosses existing koala exclusion fencing, consider appropriate access treatments such as gates to ensure the integrity of the koala-exclusion fencing	Minimises indirect impacts to koala populations due to urban development. This action is consistent with a critical action for this species under Chief Scientist Koala Report (2020)	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	CPCP Guidelines for Infrastructure Development
Infrastructure (including essential infrastructure)	Where public road infrastructure crosses koala corridors, ensure that:	Maintenance of connectivity in koala corridors, and separation of koalas from landscape threats including traffic, are	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial,	CPCP Guidelines for Infrastructure Development

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
	• Exclusion fencing is in place to prevent koalas from entering the road • Suitable koala connectivity structures are installed to protect corridor integrity	critical actions for this species under the Chief Scientist Koala Report (2020)			infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	
Urban and Industrial Infrastructure (including essential infrastructure)	A tree-felling protocol to be implemented to avoid impacts to koalas in trees that are to be cleared	A tree felling protocol to protect koalas in trees identified to be cleared on site is to provide protection to koala in the identified trees	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	DCP template Mitigation Measures Guideline CPCP Guidelines for Infrastructure Development

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
Urban and Industrial Infrastructure (including essential infrastructure)	Roadside vegetation adjacent to koala habitat areas will be managed to minimise the height of ground cover and therefore increase the visibility of any roadside fauna. Turfed areas will be mown, low ground covers will be trimmed mechanically	Visibility of koala along roadside vegetation is enhanced along motorways and roadsides for koalas crossing roadways	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	DCP template Mitigation Measures Guideline
Urban and Industrial Infrastructure (including essential infrastructure)	An onsite ecologist is to be present though the duration of pre-clearance surveys and clearing works	To protect koalas in trees identified to be cleared on site	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with	DCP template Mitigation Measures Guideline CPCP Guidelines for Infrastructure Development

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
					Appendix E of the Plan	
Urban and Industrial Infrastructure (including essential infrastructure)	Implement traffic calming measures for all development not subject to wildlife and koala exclusion fencing: Apply speed limit restrictions on local roads for areas adjacent to open space and land identified as avoided under CPCP Signpost perimeter roads and roads adjacent to wildlife habitat areas in accordance with Austroads, RMS technical guidelines, Council Guidelines and relevant Australian Standards. Install traffic calming devices such as speed humps and audible surfacing along perimeter roads adjacent to wildlife habitat	To protect koalas adjacent to or along motorways, roadsides and development	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	DCP template Mitigation Measures Guideline CPCP Guidelines for Infrastructure Development
Urban and Industrial Infrastructure (including essential infrastructure)	Install koala friendly road design structures such as underpasses, fauna bridges and overpasses consistent with any approval conditions. Reference to the RMS Biodiversity Guidelines is to be made	To protect koalas along motorways and roadsides for koalas crossing roadways	Koala	Wilton GMAC	Commitment 7: Mitigate indirect and prescribed impacts from urban, industrial, infrastructure development on the Southern Sydney koala population to best practice	DCP template Mitigation Measures Guideline CPCP Guidelines for Infrastructure Development

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
					standards and in line with advice from the Office of the NSW Chief Scientist & Engineer, and in accordance with Appendix E of the Plan	
DISEASE						
Urban and industrial, infrastructure, intensive plant agriculture	Incorporate best practice site hygiene protocols to manage the potential spread of pathogens, such as *Phytophthora* and Myrtle Rust within or adjacent to potential habitat for relevant species	Minimises the risk of the spread of pathogens due to construction activities adjacent to potential habitat for the species	Greater Glider	All nominated areas All transport corridors within and outside nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure
Transport corridors					Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat	EIA process for transport

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
OTHER						
Urban and industrial, infrastructure, intensive plant agriculture	Consult with relevant land managers to implement critical actions for Cumberland Plain Land Snail under the Save our Species program (EES, 2020) on public land adjacent to urban development during construction and operation of the development, taking into account relevant guidance in the Weed Control Strategy and the Fire Management Strategy	Minimises indirect impacts and supports maintenance of known populations adjacent to urban capable land	Cumberland Plain Land Snail	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	N/A
Urban and industrial, infrastructure, intensive plant agriculture	Implement 'open structure design' when designing structures such as roads adjacent to known populations of Cumberland Plain Land Snail where possible, consistent with the critical actions for this species under the Save our Species program (EES, 2020)	Development in the nominated areas may isolate patches of habitat. This action is consistent with a critical action for this species under the Save our Species program (EES, 2020)	Cumberland Plain Land Snail	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities	DCP

15.8.2 FLORA

The specific measures to address residual risks to flora are provided in Table 15-21.

Table 15-21: Specific mitigation measures to address residual risks – flora

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
WEED INVASION						
Transport corridors	Implement mitigation measures to manage weeds for flora populations and habitat adjacent to transport corridors during construction and operation of the development, taking into account relevant guidance in the Weed Control Strategy	Minimises indirect impacts to flora populations and habitat adjacent to transport corridors	*Dillwynia tenuifolia* *Pultenaea parviflora* *Persoonia nutans*	OSO (Wianamatta Regional Park) M7/Ropes Crossing link Road	Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat Commitment 16: Manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land	EIA process for transport
			Grevillea juniperina subsp. *juniperina*	OSO (GPEC) M7/Ropes Crossing link Road Western Sydney Freight Line		

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
			Cynanchum elegans	OSO (Cobbitty)	secured within the strategic conservation area	
Urban and industrial, infrastructure, intensive plant agriculture	Implement mitigation measures to manage weeds for flora populations and habitat adjacent to urban capable land during construction and operation of the development, taking into account relevant guidance in the Weed Control Strategy	Minimises indirect impacts to flora populations and habitat adjacent to urban capable land and supports the general environmental controls to manage weeds	*Dillwynia tenuifolia* *Grevillea juniperina* subsp. *juniperina* *Pultenaea parviflora*	GPEC WSA	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities Commitment 16: Manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the strategic conservation area	DCP EIA process for infrastructure Weed Control Strategy
			Pultenaea pedunculata	GMAC		
			Grevillea parviflora subsp. *parviflora* (important population no. 104)	Wilton		
ALTERED FIRE REGIMES						
Urban and industrial	Consult with land managers of land containing known populations or habitat for relevant species to mitigate	Minimises indirect impacts to flora populations and habitat adjacent to urban capable land	*Dillwynia tenuifolia* *Grevillea juniperina* subsp. *Juniperina* *Pultenaea parviflora*	GPEC WSA	Commitment 5: Mitigate indirect and prescribed impacts on threatened	N/A

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
	indirect impacts from fire during construction and operation of the development, taking into account guidance in the Fire Management Strategy		*Persoonia nutans*	GPEC	species, populations, and communities Commitment 18: Manage fire in strategic locations in the Cumberland subregion to support the maintenance of biodiversity values on conservation land	
			Pultenaea pedunculata	GMAC		
			Grevillea parviflora subsp. *parviflora* (important population no. 104)	Wilton		
			Persoonia bargoensis	Wilton GMAC		
HUMAN DISTURBANCE						
Urban and industrial, infrastructure, intensive plant agriculture	Consult with land managers of land containing known populations or habitat for relevant species to mitigate indirect impacts from habitat disturbance during construction and operation of the development, including controlling public access, managing maintenance activities such as mowing and weed control, and managing rubbish dumping	Minimises indirect impacts to flora populations and habitat adjacent to urban capable land	*Dillwynia tenuifolia* *Grevillea juniperina* subsp. *Juniperina* *Pultenaea parviflora*	GPEC WSA	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities Commitment 5.3 This includes consulting with public land managers to minimise exposure to human disturbance for the specified threatened species	N/A
			Persoonia nutans	GPEC		
			Grevillea parviflora subsp. *parviflora* (important population no. 104)	Wilton		
			Pultenaea pedunculata *Genoplesium baueri* (important population no. 21)	GMAC		

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
			Persoonia bargoensis *Melaleuca deanei* *Pterostylis saxicola*	Wilton GMAC		
			Pimelea spicata For this species in particular, ensure weed management activities involving the use of herbicides will minimise risks and maintain the species	All nominated areas		
HYDROLOGY						
Transport corridors	Implement mitigation measures to manage hydrology impacts to relevant flora species and habitat adjacent to transport corridors during construction and operation of the development	Minimises the risk of hydrological impacts to the species	*Cynanchum elegans*	OSO (Cobbitty)	Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat	EIA process for transport

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
SPREAD OF INFECTION/DISEASE						
Urban and industrial, infrastructure, intensive plant agriculture	Incorporate best practice site hygiene protocols to manage the potential spread of pathogens, such as Phytophthora and Myrtle Rust adjacent to potential habitat for relevant species	Minimises the risk of the spread of pathogens due to construction activities adjacent to potential habitat for the species	*Persoonia bargoensis*	Wilton GMAC	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure
			Persoonia nutans	GPEC WSA		
Transport corridors			*Persoonia nutans*	OSO (Wianamatta Regional Park)	Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat	EIA process for transport

Development type	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
OTHER						
Transport corridors	Manage key threats to the species, including: • Hydrological disturbance • Spread of weeds • Spread of infection/disease • Soil erosion and sedimentation • Ground settling or subsidence	Minimises the risk of indirect impacts during tunnel construction and operation	*Eucalyptus benthamii*	OSO tunnel	Commitments 6 and 6.2: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat	EIA process for transport
			Pimelea spicata	MRFE tunnel		
			Pomaderris brunnea	OSO tunnel		

15.8.3 THREATENED ECOLOGICAL COMMUNITIES

The specific measures to address residual risks to TECs are provided in Table 15-22.

Table 15-22: Specific mitigation measures to address residual risks – TECs

Development type	Mitigation measure	Rationale for measure	Key relevant TECs	General location of measure	Relevant commitment	Implementation mechanism
Urban and industrial, infrastructure, intensive plant agriculture	When implementing mitigation measures to manage indirect impacts to Cooks River/Castlereagh Ironbark Forest, undertake mitigation in accordance with Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest (NSW DECC, 2008) within and adjacent to the TEC	Minimises the risk of several indirect impact types on the TEC adjacent to urban development and transport corridors	Cooks River/Castlereagh Ironbark Forest (NSW and Cth)	WSA (Kemps Creek)	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure
Transport corridors				OSO (Wianamatta Regional Park)	Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat	EIA process for transport
Urban and industrial, infrastructure, intensive plant agriculture	Incorporate best practice site hygiene protocols to manage the potential spread of pathogens, such as *Phytophthora* and Myrtle Rust adjacent to potential habitat for relevant TECs	Minimises the risk of the spread of pathogens due to construction activities for urban development or transport corridors adjacent to TECs	Cooks River/Castlereagh Ironbark Forest (NSW and Cth)	WSA (Kemps Creek)	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure
			Cumberland Plain Woodland (NSW and Cth)	GPEC WSA		
			River-flat Eucalypt Forest (NSW)/Coastal Floodplain Eucalypt Forest (Cth)	All nominated areas		

Development type	Mitigation measure	Rationale for measure	Key relevant TECs	General location of measure	Relevant commitment	Implementation mechanism
			Shale Gravel Transition Forest (NSW)	GPEC WSA (Kemps Creek)		
			Shale Sandstone Transition Forest (Cth)	Wilton GMAC		
			Swamp Oak Floodplain Forest (NSW)/Coastal Swamp Oak Forest (Cth)	GPEC WSA		
Transport corridors			Cooks River/Castlereagh Ironbark Forest (NSW and Cth)	OSO (Wianamatta Regional Park)	Commitment 3: Avoid and minimise impacts to threatened species, populations, and communities within major infrastructure corridors in the nominated areas Commitment 4: Avoid and minimise impacts to threatened species, populations, and communities in the four major infrastructure corridors outside the nominated areas	EIA process for transport
			Cumberland Plain Woodland (NSW and Cth)	OSO (adjacent to WSA) Western Sydney Freight Line		
			River-flat Eucalypt Forest (NSW)/Coastal Floodplain Eucalypt Forest (Cth)	All nominated areas		
			Shale Gravel Transition Forest (NSW)	OSO (Wianamatta Regional Park)		
			Swamp Oak Floodplain Forest (NSW)/Coastal Swamp Oak Forest (Cth)	OSO (GPEC)		

15.8.4 OTHER PROTECTED MATTERS

The specific measure to address residual risks to other EPBC Act protected matters (Commonwealth land) is provided in Table 15-23.

A detailed assessment of potential indirect impacts relevant to Commonwealth land is provided in Chapter 35.

Table 15-23: Specific mitigation measures to address residual risks – other protected matters

Development type	Mitigation measure	Rationale for measure	Key relevant protected matter	General location of measure	Relevant commitment	Implementation mechanism
Urban and industrial, infrastructure, intensive plant agriculture	Ensure development adjacent to the southern and western boundaries of Commonwealth land comprising the Orchard Hills Defence Establishment mitigates impacts to surface water flows and the water quality of Blaxland Creek	Minimises the risk of indirect impacts from hydrological disturbance on an important waterway on Commonwealth land that occurs adjacent to urban development	Commonwealth land	Orchard Hills Defence Establishment	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations, and communities	DCP EIA process for infrastructure

15.9 ANALYSIS OF THREAT ABATEMENT PLANS

15.9.1 INTRODUCTION

Under the EPBC Act, the impact assessment should address whether the actions under the Plan are inconsistent with any approved Threat Abatement Plans (TAPs).

TAPs have been developed under the EPBC Act to address listed KTPs and include actions to reduce their impact on threatened species and TECs.

There are seven TAPs which address KTPs that are potentially relevant to the Plan, which are discussed below.

15.9.2 THREAT ABATEMENT PLAN FOR COMPETITION AND LAND DEGRADATION BY UNMANAGED GOATS

The goal of this is TAP is to minimise the impact of competition and land degradation by unmanaged goats (*Capra hircus*) on biodiversity. Unmanaged goats are free-living and not owned, identified, restrained or managed. Unmanaged goats can affect threatened species and TECs by:

- Grazing on threatened native vegetation and therefore preventing regeneration
- Overgrazing and causing soil erosion
- Competing with threatened fauna species for food and shelter
- Introducing weeds through seeds carried in their dung
- Polluting watercourses (DEWHA, 2008i)

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out five objectives to achieve the goal, they are:

- Prevent unmanaged goats occupying new areas and eradicate them from high conservation-value 'islands'
- Promote the maintenance and recovery of native species and ecological communities that are affected by competition and land degradation by unmanaged goats
- Improve knowledge and understanding of unmanaged goat impacts and interactions with other species and ecological processes
- Improve the effectiveness, target specificity and humaneness of control options for unmanaged goats
- Increase awareness of all stakeholders of the objectives and actions of the TAP, and of the need to control unmanaged goats (DEWHA, 2008i)

A set of actions accompanies each objective to help achieve the goal of the TAP. There are four actions to prevent unmanaged goats occupying new areas. These relate to collating data on areas of high conservation value and developing and implementing management plans for these areas.

There are three actions to promote the maintenance and recovery of native species and ecological communities that are affected by this threat. These relate to identifying priority areas to control unmanaged goats and conducting and monitoring goat control.

There are four actions to improve knowledge and understanding of unmanaged goat impacts and interactions. These relate to developing methods for assessing and monitoring the impact of unmanaged goats and improving knowledge of interactions between unmanaged goats and other key species.

There are seven actions to improve the control options for unmanaged goats. These relate to investigating ways to improve control methods and programs including:

- Improving self-mustering trap systems
- Assessing goat toxins for undesirable side effects
- Testing exclusion fence designs
- Developing training programs to help land managers
- Promoting the adoption and adaptation of the model codes of practice

There are two actions to increase awareness of stakeholders of the objectives and actions of the TAP which relate to the promotion of the objectives and actions in the TAP.

RELEVANCE OF THE TAP TO THE PLAN

There is little information to suggest that unmanaged goats are a problem in the Strategic Assessment Area and there are no activities under the Plan which are likely to lead to the introduction of unmanaged goats in the area.

The Plan has the potential to exacerbate the threat of goats to some extent and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "promote the maintenance and recovery of native species and ecological communities that are affected by competition and land degradation by unmanaged goats"

15.9.3 THREAT ABATEMENT PLAN FOR COMPETITION AND LAND DEGRADATION BY RABBITS

The goal of this TAP is to minimise the impact of competition and land degradation by rabbits (*Oryctolagus cuniculus*) on biodiversity. Rabbits are abundant in Australia and cause damage to native flora and fauna, vegetation communities and crops. Rabbits can affect threatened species and TECs by:

- Grazing on threatened native vegetation and therefore preventing regeneration
- Competing with threatened fauna species for food and shelter
- Reversing the normal processes of plant succession
- Altering ecological communities and changing soil structure and nutrient cycling, leading to significant erosion
- Removal of critical habitat for arboreal mammals and birds, leading to increased predation
- Supporting elevated population densities of pest predators such as foxes and feral cats
- Promoting growth of introduced and unpalatable species such as weeds (DoEE, 2016a)

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out four objectives to achieve the goal, they are:

- Strategically manage rabbits at the landscape scale and suppress rabbit populations to densities below threshold levels in identified priority areas
- Improve knowledge and understanding of the impact of rabbits and their interactions with other species and ecological processes
- Improve the effectiveness of rabbit control programs
- Increase engagement of the community of the environmental impacts of rabbits and the need for integrated control

A set of actions have been identified to achieve the objectives of the TAP. There are five actions to support the strategic management of rabbits at a landscape scale. These relate to identifying priority areas for rabbit control on a regional scale, coordinating efforts across all land tenures such as private land and urban areas, and developing regular monitoring and reporting mechanisms to track progress.

There are three actions to improve knowledge and understanding of the impact of rabbits. These relate to further investigating the interaction of rabbits with other species and threats to improve rabbit control measures.

There are eight actions to improve the effectiveness of rabbit control programs through further research.

There are four actions to increase communication with stakeholders around the impacts caused by rabbits. These relate to developing training programs for land managers, promoting and seeking engagement from all people in the community and promoting adoption of model codes of practice for rabbit control (DoEE, 2016a).

RELEVANCE OF THE TAP TO THE PLAN

There is no likelihood of national rabbit eradication, so rabbit control is an ongoing issue across Australia. Current rabbit control programs focus on long-term management and suppression of rabbit populations.

The Plan has the potential to exacerbate the threat of rabbits to some extent and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 1, to "strategically manage rabbits at the landscape scale and suppress rabbit populations to densities below threshold levels in identified priority areas"

15.9.4 THREAT ABATEMENT PLAN FOR DISEASE IN NATURAL ECOSYSTEMS CAUSED BY *PHYTOPHTHORA CINNAMOMI*

The goal of this TAP is to minimise the impacts of Phytophthora on EPBC-listed threatened species, TECs and MNES. The TAP applies to *Phytophthora cinnamomi,* however, other species of *Phytophthora* can also be found in Australia and may benefit from the same controls.

Phytophthora cinnamomi (Phytophthora) is a soil-borne plant pathogen, infection in plants can result in:

- Inability of infected plants to develop new shoots, flowers, fruit, and seed
- Extinction of populations of some flora species
- A dramatic modification of the native plant community's structure and composition
- A significant reduction in primary productivity and functionality
- Habitat loss and degradation of dependent flora and fauna
- Local extinction and a significant loss of genetic diversity
- Major declines in some animal species due to the loss of shelter and nesting sites or food (DoEE, 2018d)

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out four objectives to achieve the goal, they are:

- Identify and prioritise for protection biodiversity assets that are, or may be, impacted by Phytophthora. Prioritised biodiversity assets may include:
    - Listed threatened species and ecological communities
    - Areas where there is potential for Phytophthora to cause unlisted native species or ecological communities to become eligible for listing under the EPBC Act (in any category other than conservation dependent)
- Reduce the spread and mitigate the impacts of Phytophthora to protect:
    - Priority biodiversity assets
    - Areas where there is potential for Phytophthora to cause native species or ecological communities not yet listed to become eligible for listing under the EPBC Act (in any category other than conservation dependent)
- Inform and engage the community by promoting information about Phytophthora, its impacts on biodiversity and actions to mitigate these impacts
- Encourage research on Phytophthora species and options to manage infestations and protect biodiversity assets

A set of actions have been identified to achieve the objectives of the TAP. There are five actions to identify and prioritise for protection biodiversity assets that are, or may be, impacted by Phytophthora which relate to developing a list of flora, fauna and communities that are at risk and areas at risk of infection spatially to inform threat management.

There are seven actions to reduce the spread and mitigate the impacts of Phytophthora which relate to safeguarding priority biodiversity assets through adherence to hygiene protocols, integrating management of Phytophthora dieback

with other natural resource management systems (in particular fire management), and including management actions in National Recovery Plans for EPBC-listed threatened species and TECs.

There are six actions to inform and engage the community about the impacts of Phytophthora which relate to developing communication and training strategies for relevant stakeholder groups and ensuring the currency and accessibility of the relevant mapping, guidelines and signage.

There are nine actions to encourage research on Phytophthora species which relate to:

- Learning more about the Phytophthora genus
- Developing new and effective treatments for the disease
- Developing resistance and resilience in vulnerable species and communities
- Developing improved techniques for rapid diagnosis of Phytophthora infestation
- Developing restoration methods for priority sites that are degraded by Phytophthora dieback

RELEVANCE OF THE TAP TO THE PLAN

There is no effective mechanism to remove the Phytophthora pathogen from an area, and therefore the TAP aims to minimise the spread of the disease, especially when undertaking high-risk activities, such as:

- Land development
- Road construction
- Construction and maintenance of recreational tracks and walking trails
- Construction of straight-line infrastructure (for example power lines and telecommunication structures)
- Soil and gravel extraction
- Fencing
- Installation of drainage (DoEE, 2018a)

The activities above will be undertaken as part of the Plan and could exacerbate the threat of Phytophthora.

While there is a risk of the spread of Phytophthora as a result of the activities proposed in the Plan, there are commitments to manage the risk of indirect impacts due to the development under the Plan, including managing the risk of spread of Phytophthora at construction sites, and to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "protect priority biodiversity asses through reducing the spread and mitigating the impacts of *Phytophthora cinnamomi*"

15.9.5 THREAT ABATEMENT PLAN FOR INFECTION OF AMPHIBIANS WITH CHYTRID FUNGUS RESULTING IN CHYTRIDIOMYCOSIS

The goal of this TAP is to minimise the impacts of amphibian chytrid fungus (*Batrachochytrium dendrobatidis*) on affected native species and ecological communities.

Chytrid fungus causes chytridiomycosis in amphibians which is a highly infectious disease that can be found in all areas in Australia except the Northern Territory. The fungus invades the surface layers of the skin and disrupts its normal function which results in electrolyte depletion and osmotic imbalance. This can affect the nervous system of some animals and paralysis, and ultimately death, occurs. Susceptibility to the disease varies between populations but the reasons for this are unknown (DoEE, 2016b).

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out four objectives to help achieve the goal, they are:

- Improve understanding of the extent and impact of infection by amphibian chytrid fungus and reduce its spread to uninfected areas and populations
- Identify and prioritise key threatened amphibian species, populations and geographical areas and improve their level of protection by implementing coordinated, cost-effective on-ground management strategies
- Facilitate collaborative applied research that can be used to inform and support improved management of amphibian chytrid fungus
- Build scientific capacity and promote communication among stakeholders

A set of actions have been identified to achieve the objectives of the TAP. There are four actions to improve the understanding of infection by chytrid fungus and reduce its spread which relate to monitoring at-risk species, mapping the distribution of chytridiomycosis (and chytrid fungus), including control measures in amphibian translocation strategies, and ensuring appropriate hygiene protocols are implemented in chytrid-free areas.

There are six actions to support the identification and prioritisation of key threatened species, populations and geographical areas and the implementation of management strategies, which relate to completing risk assessments for high-priority species, implementing biosecurity measures around high-priority areas, and coordinating conservation efforts.

There are seven actions to facilitate research to improve management of chytrid fungus which include obtaining knowledge on:

- Assisted colonisation strategies
- The mechanisms for resistance
- The severity of chytrid fungus
- The best treatment protocols

There are three actions to build scientific capacity and promote communication among stakeholders which relate to developing an effective communication strategy, supporting a central information storage site, and encouraging participation in the National Chytrid Working Group.

RELEVANCE OF THE TAP TO THE PLAN

Most of populations susceptible to chytrid fungus that occur adjacent to or within proximity to proposed development, such as the Green and Golden Bell Frog, already exist within a highly built up and urbanised environment. Development under the Plan is unlikely to change the current level of risk in these areas in relation to chytrid fungus.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "identify and prioritise key threatened amphibian species, populations and geographical areas and improve their level of protection by implementing coordinated, cost-effective, on-ground management strategies"

15.9.6 THREAT ABATEMENT PLAN FOR PREDATION BY EUROPEAN RED FOX

The goal of this TAP is to minimise the impact of the European red fox (*Vulpes Vulpes*) on biodiversity in Australia.

The European red fox can be found all over the Australian mainland, apart from in the far North. Fox predation is a threat to many threatened fauna species, in particular terrestrial mammals and ground-nesting birds.

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out four objectives to achieve the goal, they are:

- Prevent foxes occupying new areas in Australia and eradicate foxes from high-conservation-value 'islands'
- Promote the maintenance and recovery of native species and ecological communities that are affected by fox predation
- Improve knowledge and understanding of fox impacts and interactions with other species and other ecological processes
- Improve the effectiveness, target specificity, integration, and humaneness of control options for foxes
- Increase awareness of all stakeholders of the objectives and actions of the TAP, and of the need to control and manage foxes

A set of actions have been identified to help achieve the objectives of the TAP. There are four actions to prevent foxes occupying new areas in Australia which relate to collating data on areas with high conservation values, developing and implementing management plans, and eradicating populations of foxes from lands adjacent to priority areas.

There are three actions to promote the recovery of native species and ecological communities that are affected by fox predation which relate to identifying priority areas for fox control and undertaking and monitoring fox control at these locations.

There are five actions to improve the knowledge and understanding of fox impacts which relate to developing methods for monitoring foxes, exploring the interactions between foxes, feral cats, wild dogs, and rabbits, and estimating the costs of impacts from foxes.

There are seven actions to improve the control options for foxes which relate to investigating existing and new control techniques, developing training programs for land managers, and promoting best practice standards.

There is one action to increase awareness of the need to control and manage foxes which relates to ensuring that the actions in the TAP are better communicated.

RELEVANCE OF THE TAP TO THE PLAN

The Plan has the potential to exacerbate the threat of foxes to some extent and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "promote the maintenance and recovery of native species and ecological communities that are affected by fox predation"

15.9.7 THREAT ABATEMENT PLAN FOR PREDATION BY FERAL CATS

The goal of this TAP is to minimise predation of native species by feral cats (*Felis catus*).

Feral cats are found throughout all habitats in mainland Australia and Tasmania and on some offshore islands. They are known to have a devastating effect on native fauna, predominantly from predation but also through competition and disease transmission (DoE, 2015e).

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out four objectives to achieve the goal, they are:

- Effectively control feral cats in different landscapes
- Improve effectiveness of existing control options for feral cats
- Develop or maintain alternative strategies for threatened species recovery
- Increase public support for feral cat management and promote responsible cat ownership

A set of actions have been identified to help achieve the objectives of the TAP. There are nine actions to improve the control of feral cats in different landscapes which relate to further research and development of current and new feral cat control options, improving understanding of the interactions between feral cats and other predators, and development of Code of Practice and/or Standard Operating Procedures for new tools.

There are four actions to improve the effectiveness of existing feral cat control options which relate to understanding how best to encourage land managers to include cat management programs within their activities, providing information regarding best practice methods and standard operating procedures, and implementing a consistent regulatory approach across all state and territory governments.

There are five actions to support the investigation of alternative strategies for threatened species recovery which include eradicating or controlling cats in priority areas, implementing, or improving biosecurity measures in cat-free areas, and creating fenced reserves to support the recovery of threatened species.

There are four actions to increase public support for cat management which relate to increasing awareness and understanding about:

- The threat to biodiversity posed by cats
- The need for responsible cat ownership
- The containment of cats where their roaming may impact priority areas

RELEVANCE OF THE TAP TO THE PLAN

Total eradication of feral cats is not currently feasible and cat control is an ongoing issue across Australia. Current control programs focus on long-term management and suppression of feral cat populations.

Existing land use within the nominated areas and surrounding region includes residential areas and farming, which means cats are unlikely to pose a novel threat to native fauna in the area. However, the extent of proposed new urban development under the Plan means the threat is likely to be exacerbated. The main areas of concern relate to new urban development in Wilton and the southern section of GMAC, where the current density of houses is low.

The Plan includes a commitment to manage indirect impacts due to development under the Plan, including to ensure that:

- Domestic animals are appropriately contained at urban/bushland interfaces
- Property boundaries should have appropriate fencing to contain domestic animals within the landholders' property

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 4, to "increase public support for feral cat management and promote responsible cat ownership"

15.9.8 THREAT ABATEMENT PLAN FOR PREDATION, HABITAT DEGRADATION, COMPETITION AND DISEASE TRANSMISSION BY FERAL PIGS (*SUS SCROFA*)

The goal of this TAP is to prevent further species and ecological communities from becoming threatened or extinct due to the impacts of feral pigs.

Feral pigs are widespread throughout Australia and can affect threatened species and ecological communities by:

- Consuming threatened fauna species
- Destroying threatened flora species
- Altering ecological parameters such as plant species composition and succession, nutrient and water cycles, and water quality
- Changing the composition of threatened plant communities
- Altering soil structure
- Increasing the spread of weeds

- Spreading animal diseases such as leptospirosis, brucellosis, and plant pathogens such as *Phytophthora cinnamomi*

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out six objectives to achieve the goal, they are:

- Prioritise key species, ecological communities, ecosystems, and locations across Australia for strategic feral pig management
- Encourage the integration of feral pig management into land management activities at regional, state and territory, and national levels
- Encourage further scientific research into feral pig impacts on nationally threatened species and ecological communities, and feral pig ecology and control
- Record and monitor feral pig control programs, so their effectiveness can be evaluated
- Build capacity for feral pig management and raise feral pig awareness amongst landholders and land managers
- Improve public awareness about feral pigs and the environmental damage and problems they cause, and the need for the feral pig control

A set of actions have been identified to help achieve the objectives of the TAP. There are two actions to support strategic feral pig management which include identifying priority species, ecological communities, ecosystems, and locations for priority protection, and implementing control measures in these areas.

There is one action to support the integration of feral pig management into land management activities which relates to encouraging government departments and agencies, and regional groups, to integrate feral pig management into their land management activities.

There are four actions to encourage further scientific research into feral pig impacts which include undertaking more research into:

- Feral pig impacts
- Feral pig population dynamics and ecology
- Special and temporal use of landscapes by feral pigs
- The effectiveness of feral pig control methods

There are three actions to evaluate the effectiveness of feral pig control programs which relate to developing better monitoring techniques and encouraging centralised recording of feral pig control actions.

There are two actions to raise feral pig awareness amongst landholders and land managers which relate to increased delivery of training programs to build feral pig management skills and improve the understanding of special impediments to feral pig control.

There are two actions to improve public awareness about feral pigs which include developing a public education program about feral pigs and the environmental damage and problems they could cause.

RELEVANCE OF THE TAP TO THE PLAN

Feral pigs are widely established in Australia and it is not currently possible to completely eradicate them (DoEE, 2017).

The Plan has the potential to exacerbate the threat of feral pigs to some extent and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "encourage the integration of feral pig management into land management activities at regional, state and territory, and national levels"

16 Adaptive management for addressing uncertainty

This Chapter:

- Discusses what is adaptive management and why it is important
- Sets out the regulatory requirements for adaptive management under the BAM and ToR
- Identifies key uncertainties and risks in implementation
- Describes the Plan's approach to adaptive management
- Assesses the adequacy of the Plan's approach to adaptive management

The analysis in this Chapter is supported by the detailed evaluation of the Plan in Part 7.

16.1 WHAT IS ADAPTIVE MANAGEMENT AND WHY IS IT IMPORTANT

Adaptive management is a process for improving management practices through learning from the outcomes of previous management (DSEWPC, 2011). It is based on information derived from monitoring and can be applied anywhere uncertainty in management exists. Adaptive management typically involves the following steps:

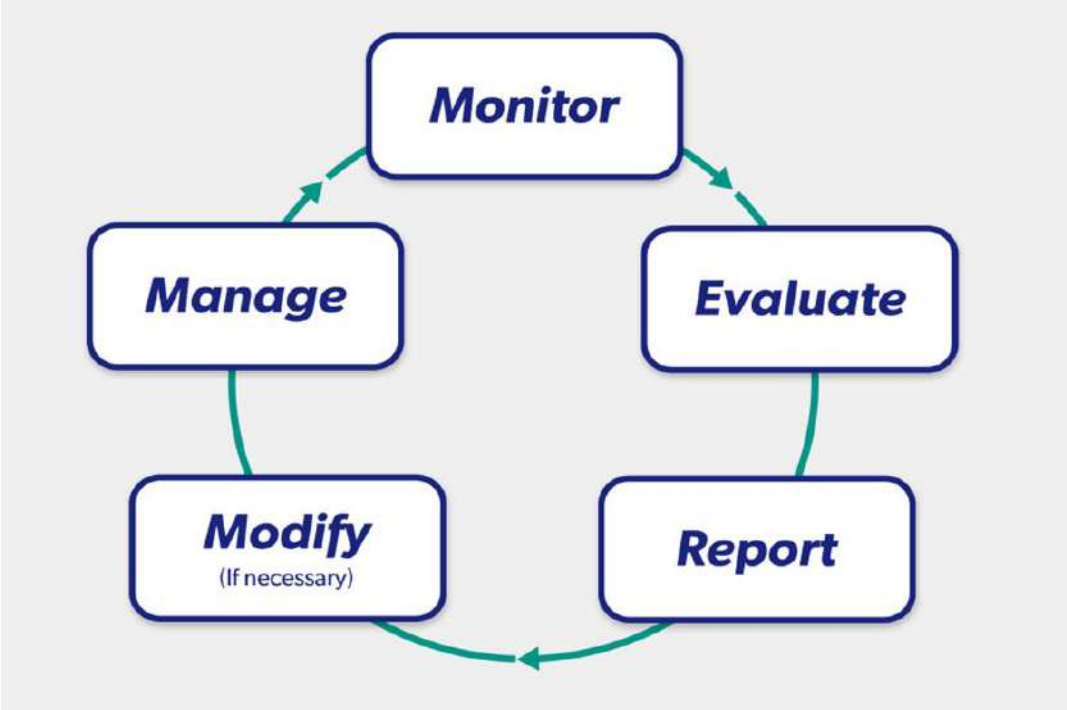

Figure 16-1: Adaptive management steps (taken from Sub-Plan B)

Adaptive management is an essential part of the implementation framework for strategic assessments. It is important because:

- The scale and complexity of strategic assessments means that there may be uncertainty relating to some impacts during the assessment process that need to be addressed during implementation
- The timeframes for strategic assessments are long and implementing agreed outcomes will be subject to a range of uncertainties over the life of the Plan
- Factors relating to the environment are likely to change over the life of a strategic assessment and an adaptive approach to management will be important for achieving the Plan's outcomes
- Changes to State and Commonwealth legislation, policies, plans and advice will occur over the life of the Plan

Providing a process to address uncertainty and deal with changing circumstances during the life of the Plan is therefore critical.

16.2 REGULATORY REQUIREMENTS

The BAM and ToR both require the Assessment Report to demonstrate how uncertainty will be addressed through adaptive management during implementation.

The BAM applies a narrower focus around just dealing with uncertain impacts, while the ToR has a broader focus on addressing uncertainty across all elements of implementation (including conservation commitments and actions).

16.2.1 BC ACT REQUIREMENTS

BAM

Section 9.4 of the BAM requires the BCAR to outline the adaptive management strategy proposed for minimising impacts that are uncertain. The BAM identifies the following impacts on biodiversity that are uncertain:

- Impacts related to damage to karst, caves, crevices, cliffs, and other geological features of significance
- Impacts related to subsidence and upsidence resulting from underground mining
- Impacts related to wind turbine strikes
- Impacts related to vehicle strikes

Impacts related to vehicle strikes is the only relevant consideration for development within the nominated areas. Mining and the construction of wind turbines are not within the scope of the project and are not considered further.

Chapter 24 (Prescribed Biodiversity Impacts) examines the potential for impacts related to karst, caves, crevices, cliffs, and other geological features of significance. It concludes that impacts to these features will not occur within the nominated areas, and it is therefore not considered further in this chapter.

GUIDELINES

In addition to the BAM, the draft *Guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification* (version 6) provide a set of guiding principles for demonstrating that commitments and actions proposed for a strategic biodiversity certification adequately address impacts on biodiversity values.

The last principle relates to certainty of implementation and requires that:

> *"Principle 8 – The delivery of conservation measures is timely and certain"*

16.2.2 EPBC ACT REQUIREMENTS

Section 6 of the ToR requires the SAR to identify key uncertainties and risks associated with implementing the Plan and describe and assess the adequacy of the procedures proposed in the Plan to ensure an adaptive approach to implementation of the Plan.

The relevant ToR are:

> *6.1 The Report must identify key uncertainties and risks associated with implementing the Plan, responses to these and proposed adaptations to changing circumstances. Key uncertainties may include:*
>
> - *Knowledge gaps in scientific understanding and responding to new knowledge.*
> - *Assumptions made in assessing potential impacts and benefits.*
> - *How changes to State and Commonwealth legislation, policies, plans, and advice is to be accounted for in the management of the areas impacted by the Plan.*
> - *Effectiveness or capacity to ensure the Plan is implemented.*
>
> *6.2 The Report must describe and assess the adequacy of the procedures proposed in the Plan to ensure an adaptive approach to implementation of the Plan. This must include:*
>
> 1. *How the results of monitoring will be used to understand the effectiveness of conservation outcomes for protected matters and improve implementation.*

2. *How new information relating to protected matters and biodiversity, including legislative changes, may be assessed and accounted for in implementation of the Plan.*

16.3 KEY UNCERTAINTIES AND RISKS IN IMPLEMENTATION

The ToR (Clause 6.1) provide a framework for identifying the key uncertainties and risks in implementation. This framework includes BAM requirements around uncertain impacts and is addressed below.

16.3.1 KNOWLEDGE GAPS IN SCIENTIFIC UNDERSTANDING AND RESPONDING TO NEW KNOWLEDGE

KNOWLEDGE GAPS IN SCIENTIFIC UNDERSTANDING

There are two key types of gaps in scientific understanding relevant to the assessment:

- Data gaps
- Gaps in understanding of ecological processes

Data gaps

Data gaps for this assessment can be defined as a lack of information about a particular element of the environment. For example, presence or absence information for a threatened species at a particular site may not be available at the time required.

Given the large spatial scale of the Plan, it is not possible to have perfect information about the environment and some level of uncertainty in data is inherent in the project. However, the requirements of the BAM and the ToR define what is an acceptable level of data to understand the environment and to conduct the assessment. As outlined in Part 3, a comprehensive data set has been collected for the assessment which addresses the BAM and ToR.

The data that has been used in the assessment and any limitations are discussed in detail in:

- Chapter 13: Data and limitations
- Individual assessment chapters for protected matters

Understanding of ecological processes

Sufficient understanding of ecological processes is a key challenge for all environmental impact assessments. There is commonly a lack of information about issues such as:

- Species distribution
- Species habitat requirements
- Species population numbers and dynamics
- The effects of key threatening processes (e.g. climate change)
- The best approaches for minimising and mitigating potential impacts

The assessment addresses these uncertainties through:

- Gathering the best available information from scientific literature, expert knowledge, on-ground surveys
- Applying a precautionary approach to understanding and evaluating potential impacts. An analysis of the application of the precautionary principle is provided in Part 7

The Plan addresses uncertainty through its monitoring, evaluation, and reporting (MER) framework combined with ongoing adaptive management.

RESPONDING TO NEW KNOWLEDGE

Given the long timeframe of the Plan, new knowledge about environmental issues will become available through:

- New scientific research
- Monitoring as part of implementation of the Plan

It will be critical that the Plan can consider this information and respond appropriately. The Plan's approach to this is discussed below in Section 16.4.

16.3.2 ASSUMPTIONS MADE IN ASSESSING POTENTIAL IMPACTS AND BENEFITS

One of the key risks in environmental impact assessment is making incorrect assumptions about the nature of potential impacts and benefits of a project. In particular, it is important that the consequences of potential impacts are not understated, and the benefits of conservation measures are not overstated.

To address this risk, the assessment report takes a precautionary approach to identifying and analysing impacts and benefits. For example, the habitat mapping for threatened species generally overestimates the amount of habitat in the Plan Area which means the impacts that are assessed are likely to be larger than what will ultimately occur on the ground.

The assumptions made in assessing potential impacts and benefits are:

- Outlined in Part 3 – Assessment Approach which describes the methods used in the assessment
- Set out in relation to each protected matter in the individual assessment chapters

The application of the precautionary principle to the assessment is evaluated in Part 7.

16.3.3 HOW CHANGES TO STATE AND COMMONWEALTH LEGISLATION, POLICIES, PLANS AND ADVICE IS TO BE ACCOUNTED FOR IN THE MANAGEMENT OF THE AREAS IMPACTED BY THE PLAN

Given the long timeframes of the Plan, changes to legislation, policies, plans, and advice are inevitable. These changes may lead to risks around:

- Implementation processes. For example, changes to State planning policies may affect the approaches to addressing indirect impacts
- Conservation priorities for threatened species and ecological communities. For example, changes to a Conservation Advice may provide new information about the key threats to a species and the recommended mitigation strategies
- Compliance. For example, changes to legislation may have implications for compliance under what would then be an approval under outdated legislation

The Plan addresses these risks through:

- Clearly establishing outcomes and commitments that will be delivered despite any changes to legislation, policies, plans and advice
- Its approach to MERI and adaptive management (discussed in Section 9.5 and in Section 16.4 below) which will provide a way of responding to any changes to legislation, policies, plans and advice

16.3.4 EFFECTIVENESS OR CAPACITY TO ENSURE THE PLAN IS IMPLEMENTED

Effective implementation is particularly important for strategic assessments because of the size and complexity of the programs, the long timeframes over which they are implemented, the number of stakeholders and the diversity of their interests, the amount of money the programs cost, and the complexity of the legal frameworks they operate within.

Lessons learnt from other strategic assessments around Australia suggest that effective implementation requires:

- Clear and feasible outcomes that the Plan will deliver
- Clarity about the delivery framework and mechanisms to implement the Plan
- Appropriate flexibility within the Plan to ensure it remains relevant over time
- Clear governance arrangements, including certain funding
- Comprehensive processes to monitor and report on implementation, and adapt implementation as needed

The Plan has been designed to address these issues. A detailed evaluation of the implementability of the Plan is provided in Chapter 41.

16.4 THE PLAN'S APPROACH TO ADAPTIVE MANAGEMENT

The Plan includes a commitment (Commitment 25) to "implement an evaluation program for the Plan that sets out requirements for monitoring, evaluation, reporting and adaptive management". The approach to adaptive management is set out in Sub-Plan A. The approach is designed around:

- Clearly defining outcomes through program logic
- Undertaking regular data collection/monitoring to track progress
- Completing regular evaluations to investigate cause and effect, efficiency and effectiveness, and test assumptions
- Establishing programs of research to test and improve management interventions

Adaptive management will be applied across the entire conservation program. It will use the data sourced through monitoring and the findings of program evaluation to determine if actions need to be revised to more-effectively deliver the Plan's commitments (and consequently the Plan's outcomes). Evaluations will consider any new information that becomes available over the life of the Plan (in addition to monitoring data). Information about the Plan's approach to MERI is provided in Part 2 and evaluated in Part 7.

Where evaluation suggests a commitment is not tracking as planned, it will trigger a review and potential modification to the required action or delivery of action. This process will include delivery partners as appropriate.

Changes to actions may be made in the case that:

- Targets are not being met
- The program logic does not adequately translate into the desired outcomes (i.e. the commitments are not leading to the outcomes as anticipated)
- External factors arise that affect the assumptions, logic, or delivery of the Plan. This may relate to large-scale changes (e.g. unpredicted climate variation) or smaller scale changes (e.g. local events such as fires, floods or disease)

One particularly important part of the adaptive management process will be a series of adaptive management steps that will be triggered in the case that biodiversity offsets are not secured in line with development impacts. Where the total amount of secured offsets is less than 80 per cent of the offset liability at a point in time, the following adaptive management steps will be implemented:

- Property acquisition by agreement
- Compulsory acquisition of property
- Land use planning responses to development

These steps will not be implemented within the first 5 years to allow time for the Plan to be implemented and offsets established unless the executive implementation committee decides to initiate them. After 5 years, the steps will be triggered as outlined above.

16.5 ADEQUACY OF THE PLAN'S APPROACH TO ADAPTIVE MANAGEMENT

Adaptive management under the Plan will use data from monitoring and the findings of program evaluations to determine whether actions need to be revised to achieve the commitments and outcomes more effectively.

Where an evaluation indicates a commitment or outcome is not being effectively and efficiently delivered or achieved, the Plan specifies that this will trigger a detailed review of implementation. This will be carried out by the relevant delivery agency for that particular project or program, in partnership with the Department.

The Plan specifies that adaptive responses may be triggered where:

- Offset targets are not being met
- External factors arise that affect the assumptions, logic, or delivery of the Plan

The Plan's approach to adaptive management is considered appropriate because:

- There is a clear commitment in the Plan to take an adaptive approach to ensure the outcomes and commitments are delivered
- The approach addresses the key uncertainties and risks in implementation of the Plan
- The approach is supported by:
    - Clear processes and steps as part of the MERI framework
    - The broader governance arrangements of the Plan which identify roles and responsibility for implementation
    - Commitments to fund implementation of the Plan

Further evaluation of the adequacy of the plan's approach to adaptive management is provided in Chapter 7.

Part 4 Attachment List of Tables

A. Indirect impacts relevant to each species and TEC

Identification of indirect impacts relevant to each matter is presented in:

- Table A-1 – NSW-listed threatened fauna
- Table A-2 – NSW-listed threatened flora
- Table A-3 – NSW-listed TECs

Table A-1: Potential indirect impacts which may affect threatened fauna

Scientific name	Common name	Cth status	NSW status	BAM species type	Hydrology / soil disturbance	Ground subsidence	Spread of infection / disease	Spread of weeds	Pest / domestic animals	Altered fire regimes	Increased public access / disturbance	Fauna mortality / barriers to movement	Fauna disturbance due to noise, dust or light	Inadvertent impacts on adjacent habitat

DATE:	2021

Part 5A Contents

Part 5A List of Figures

Part 5A List of Tables

17 Introduction

This Part describes the existing biodiversity values within the nominated areas for matters listed under the *Biodiversity Conservation Act 2016* (BC Act) in accordance with the Biodiversity Assessment Method 2017 (BAM), including:

- Landscape features and site context
- Native vegetation, including native vegetation extent, type and condition
- NSW listed Threatened Ecological Communities (TECs)
- NSW listed threatened species and habitat

The BAM uses the term Subject Land to mean land to which the BAM is applied in Stage 1 to assess the biodiversity values of the land, including land within urban capable land or proposed for biodiversity certification. In this Assessment Report, the terms 'nominated areas' and 'urban capable land' are used instead of the term Subject Land.

18 Landscape features and site context

This Chapter provides an assessment of the landscape features and site context of the nominated areas in accordance with section 4 of the BAM, including:

- Interim Biogeographic Regionalisation of Australia (IBRA) bioregions and subregions
- Native vegetation extent – buffer area
- NSW (Mitchell) Landscapes
- Rivers and streams
- Wetlands
- Habitat connectivity and fragmentation
- Areas of geological significance and soil hazards
- Areas of outstanding biodiversity value
- Site context

These landscape features are shown in the site and location maps for each nominated area:

- Wilton: Figure 18-1 (site map) and Map 18-1 (location map)
- GMAC: Figure 18-2 (site map) and Map 18-2 (location map)
- WSA: Figure 18-3 (site map) and Map 18-3 (location map)
- GPEC: Figure 18-4 (site map) and Map 18-4 (location map)

18.1 IBRA BIOREGIONS AND SUBREGIONS

The nominated areas occur within the Sydney Basin IBRA bioregion (version 7) and the Cumberland and Cataract subregions. The percentages of each subregion within each nominated area are shown in Table 18-1.

Table 18-1: Percent of nominated areas representing each subregion

Nominated area	Subregion	Per cent of nominated area within each subregion
Wilton Growth Area (Wilton)	Cumberland	98.46
	Sydney Cataract	1.54
Greater Macarthur Growth Area (GMAC)	Cumberland	96.45
	Sydney Cataract	3.55
Western Sydney Aerotropolis (WSA)	Cumberland	100.00

Nominated area	Subregion	Per cent of nominated area within each subregion
Greater Penrith to Eastern Creek Growth Area (GPEC)	Cumberland	100.00

The Sydney Basin bioregion lies on the central east coast of NSW and covers an area of approximately 3,624,008 hectares. It occupies about 4.53 per cent of NSW and is one of three bioregions contained wholly within the State.

The Sydney Basin bioregion extends from just north of Batemans Bay to Nelson Bay on the lower North Coast, and west to Merriwa. It is bordered to the north mostly by the NSW North Coast and Brigalow Belt South bioregions, to the south by the South East Corner bioregion and to the west by the South Eastern Highlands and NSW South Western Slopes bioregions. The bioregion is one of the most species-diverse in Australia (OEH, 2016).

The Cumberland subregion geology is dominated by Triassic age Wianamatta Group shales and lithic sandstones. Quaternary alluvium occurs along the main streams and a large plume of Tertiary-era sandy and gravelly alluvium occurs in the northern end between Wianamatta (South Creek) and the Nepean/Hawkesbury River. The characteristic landform is low rolling hills and wide valleys within a rain shadow area between the Blue Mountains and the coast. There are also swamps and lagoons on the floodplain of the Nepean and Hawkesbury Rivers and major creeks including Wianamatta (South Creek).

Typical soils of the Cumberland subregion are red and yellow texture contrast soils on slopes, becoming harsher and sometimes affected by dryland salinity in tributary valley floors. There is uniform red to brown clays and poor uniform stony soils, often with texture contrast profiles on older gravels with high quality loams on modern floodplain alluvium (DPIE, 2019).

Characteristic landforms of the Cumberland subregion include low rolling hills and wide valleys in a rain shadow area below the Blue Mountains. At least three terrace levels are evident in the gravel splays which occur within the subregion. Swamps and lagoons occur on the floodplain of the Nepean River. Typical vegetation of the Cumberland subregion includes Grey Box, Forest Red Gum, Narrow-Leaved Ironbark woodland to open forest with some Spotted Gum on the shale hills. Hard-leaved Scribbly Gum, Narrow-leaved Apple and Old Man Banksia occur on alluvial sands and gravels. Broad-Leaved Apple, Cabbage Gum and Forest Red Gum with abundant Swamp Oak occur on low-lying flats. Tall Spike Rush, and *Juncus* sp. with Swamp Oak occur in lagoons and swamps (OEH, 2016).

The Sydney Cataract subregion occurring to the south-east of Wilton and the east of GMAC is Triassic era geology with Hawkesbury Sandstone on the coastal edge of the Sydney Basin above the Illawarra escarpment. The characteristic landform is a sandstone plateau with shallow creeks flowing through hanging swamps in the highest parts, ramping down to low hills in the Georges River and Botany Bay. There are coastal cliffs north of the Illawarra and a large barrier system with beach, dunes, swamps, and estuary at the westernmost edge of Kurnell.

Typical soils of the Sydney Cataract subregion are deep sands and clayey sands with peat in hanging swamps, yellow earths on better drained sandstone ridges. Siliceous sands occur in younger dunes and well-developed podzols occur in older dunes.

Characteristic landforms of the Sydney Cataract include a sandstone plateau with shallow creeks flowing through hanging swamps in the highest part of the subregion, ramping down to low hills in the Georges River and Botany Bay areas. Coastal cliffs occur to the north of the Illawarra and a large barriers system with dunes, swamps and estuary occurs at Kurnell. Vegetation of the Sydney Cataract subregion is typically Red Bloodwood and Silvertop Ash Woodland with abundant shrubs on sandstone and extensive *Gahnia* and *Banksia* in hanging swamps. There is a coastal dune sequence of Tea-Tree, Coast Wattle, Smooth-Barked Apple, Blackbutt and Swamp Mahogany on the barrier system (OEH, 2016).

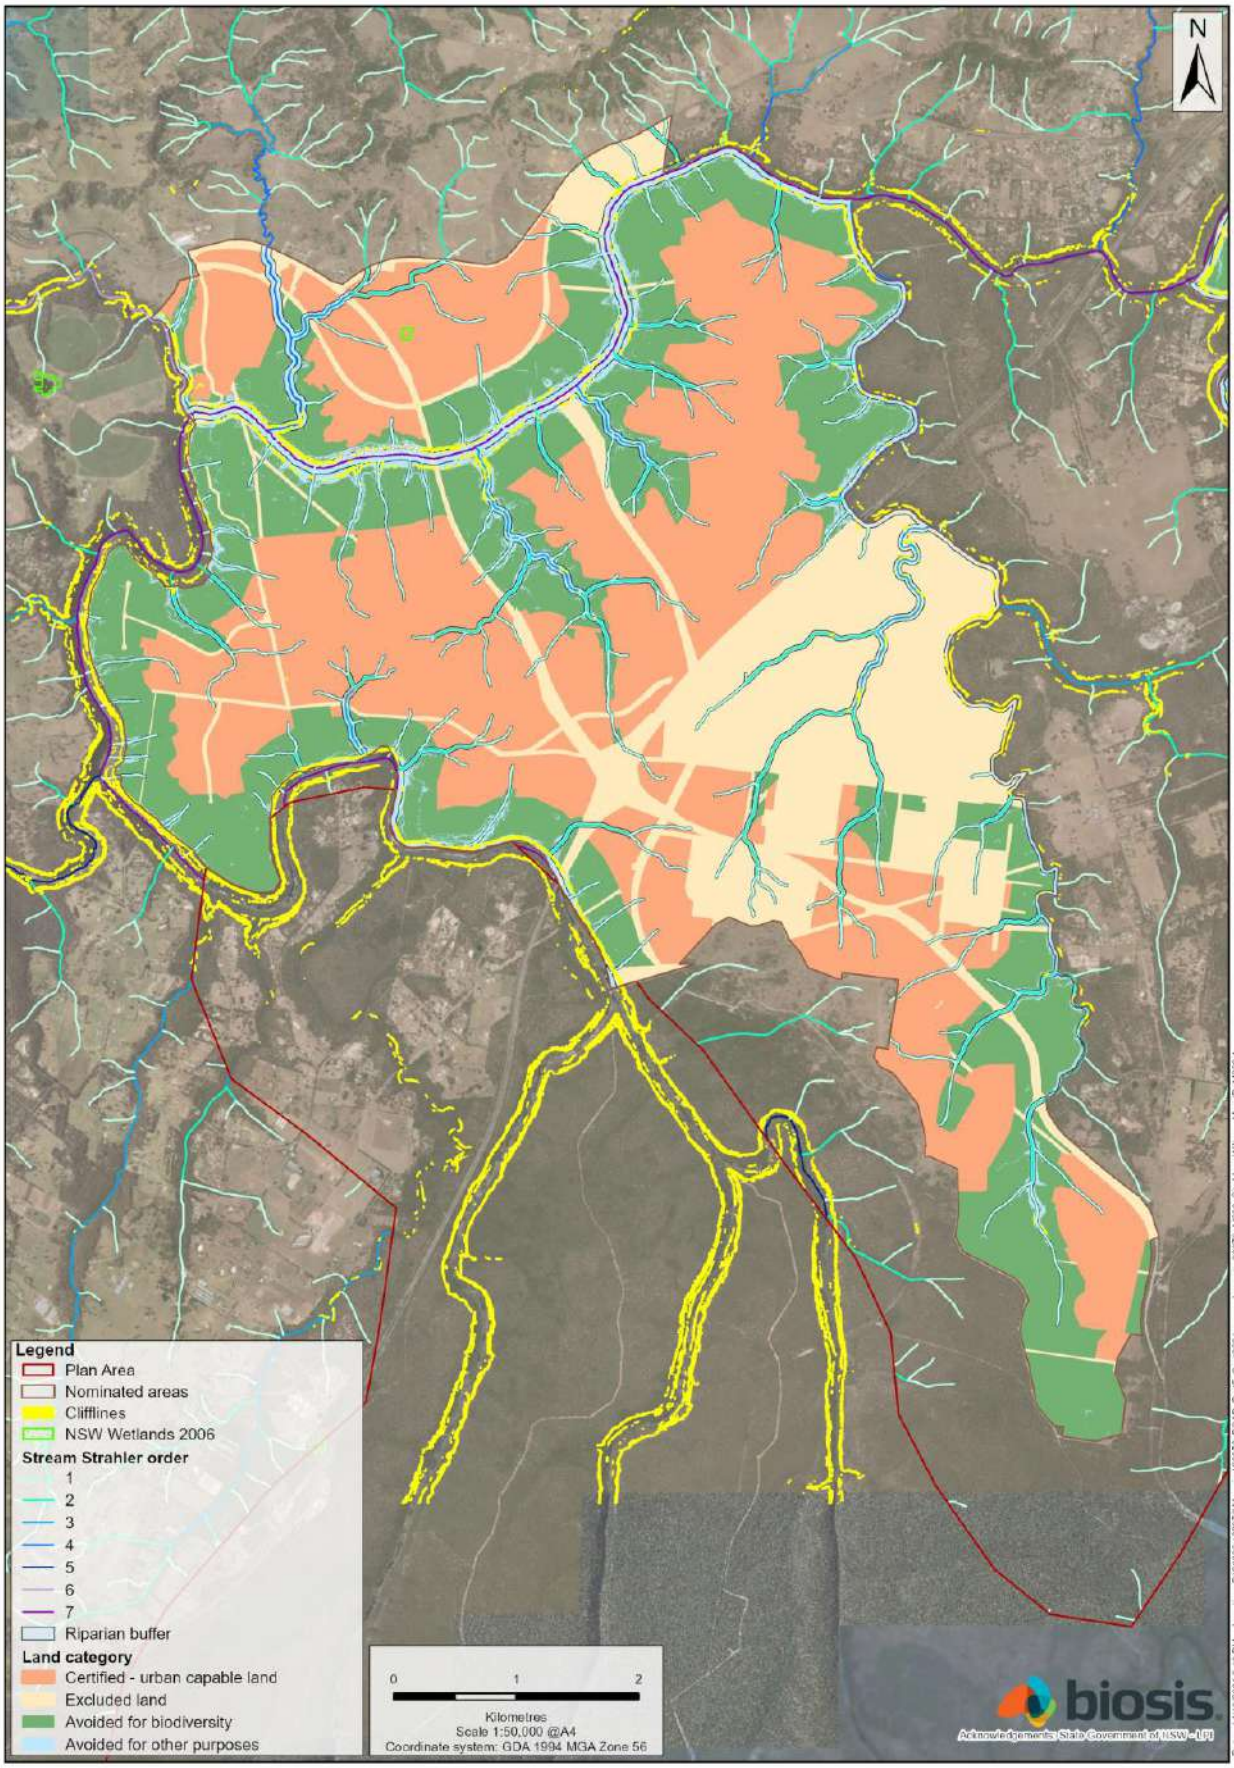

Figure 18-1: Site map – Wilton

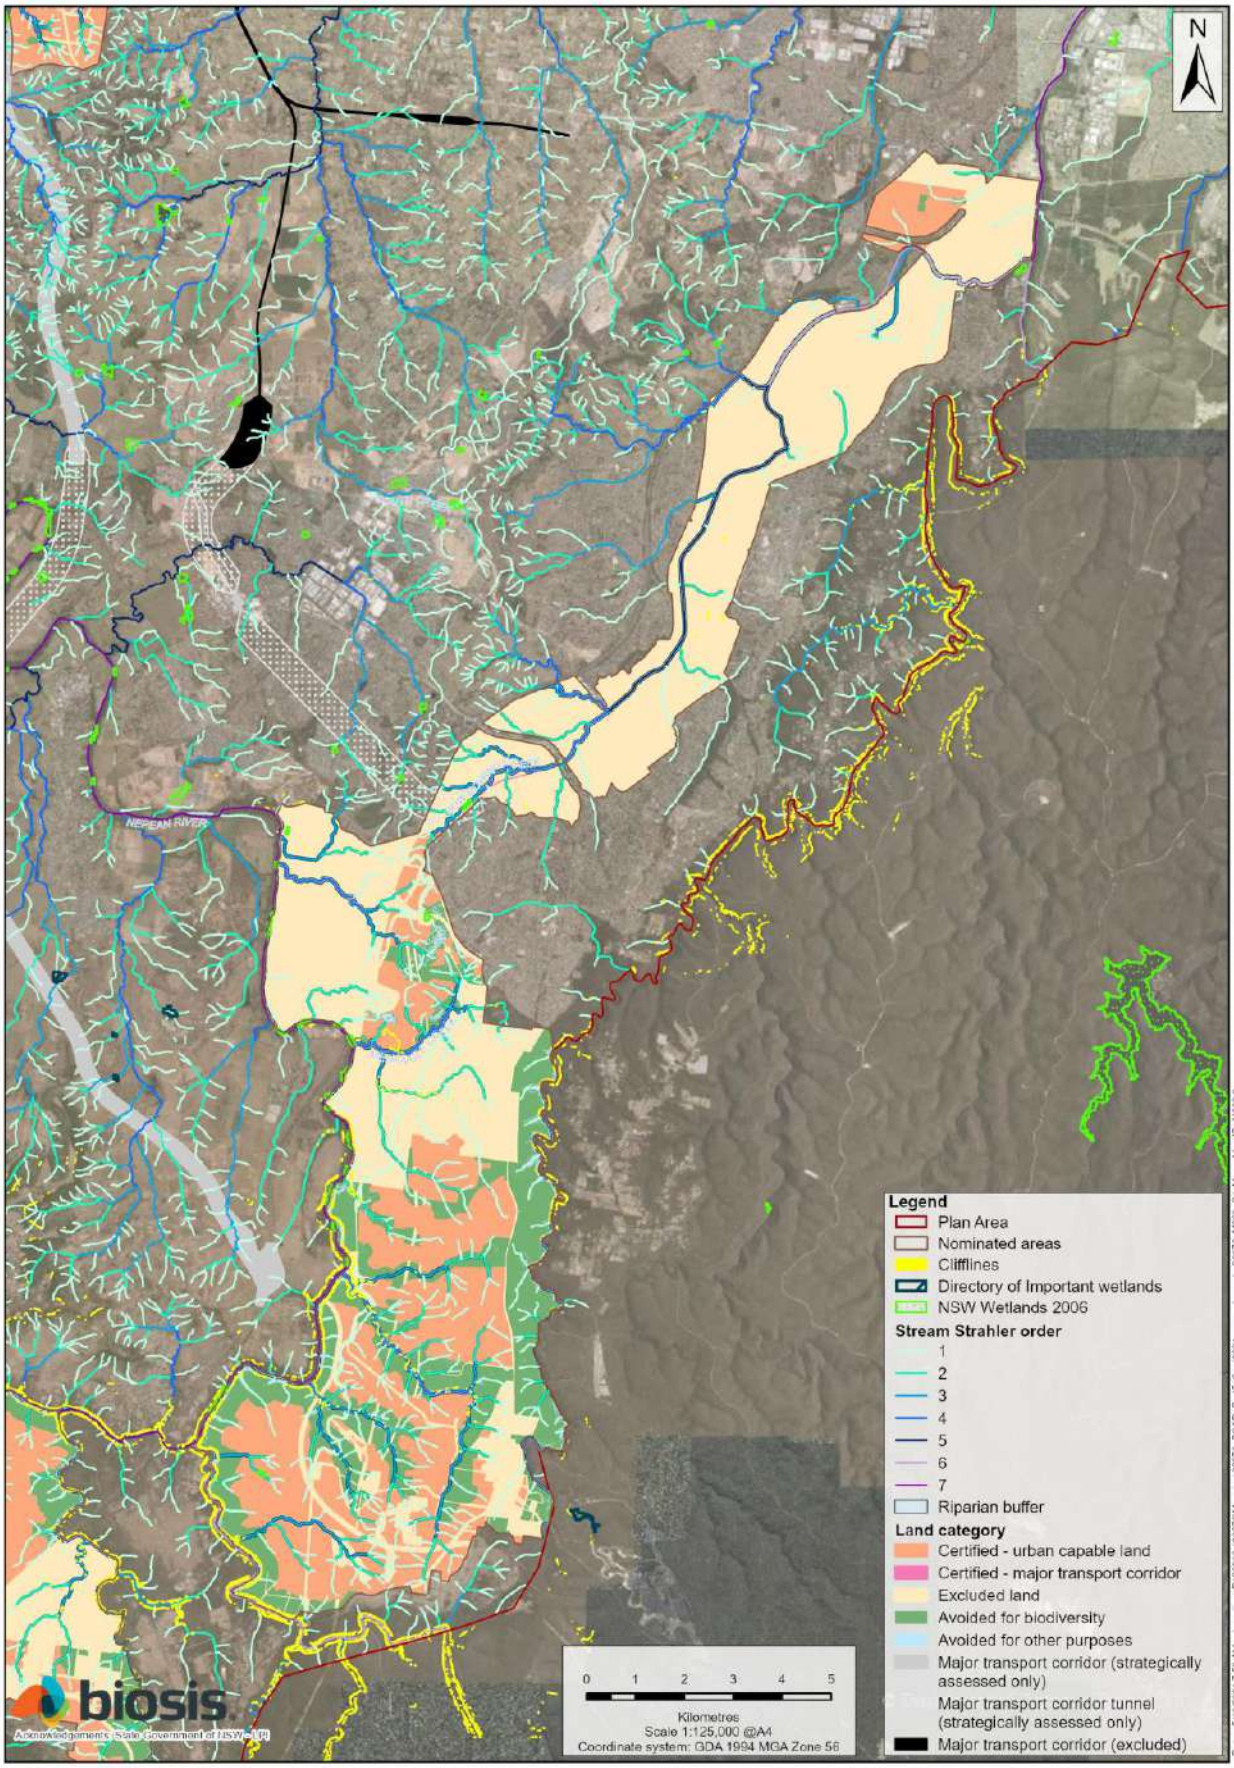

Figure 18-2: Site map – GMAC

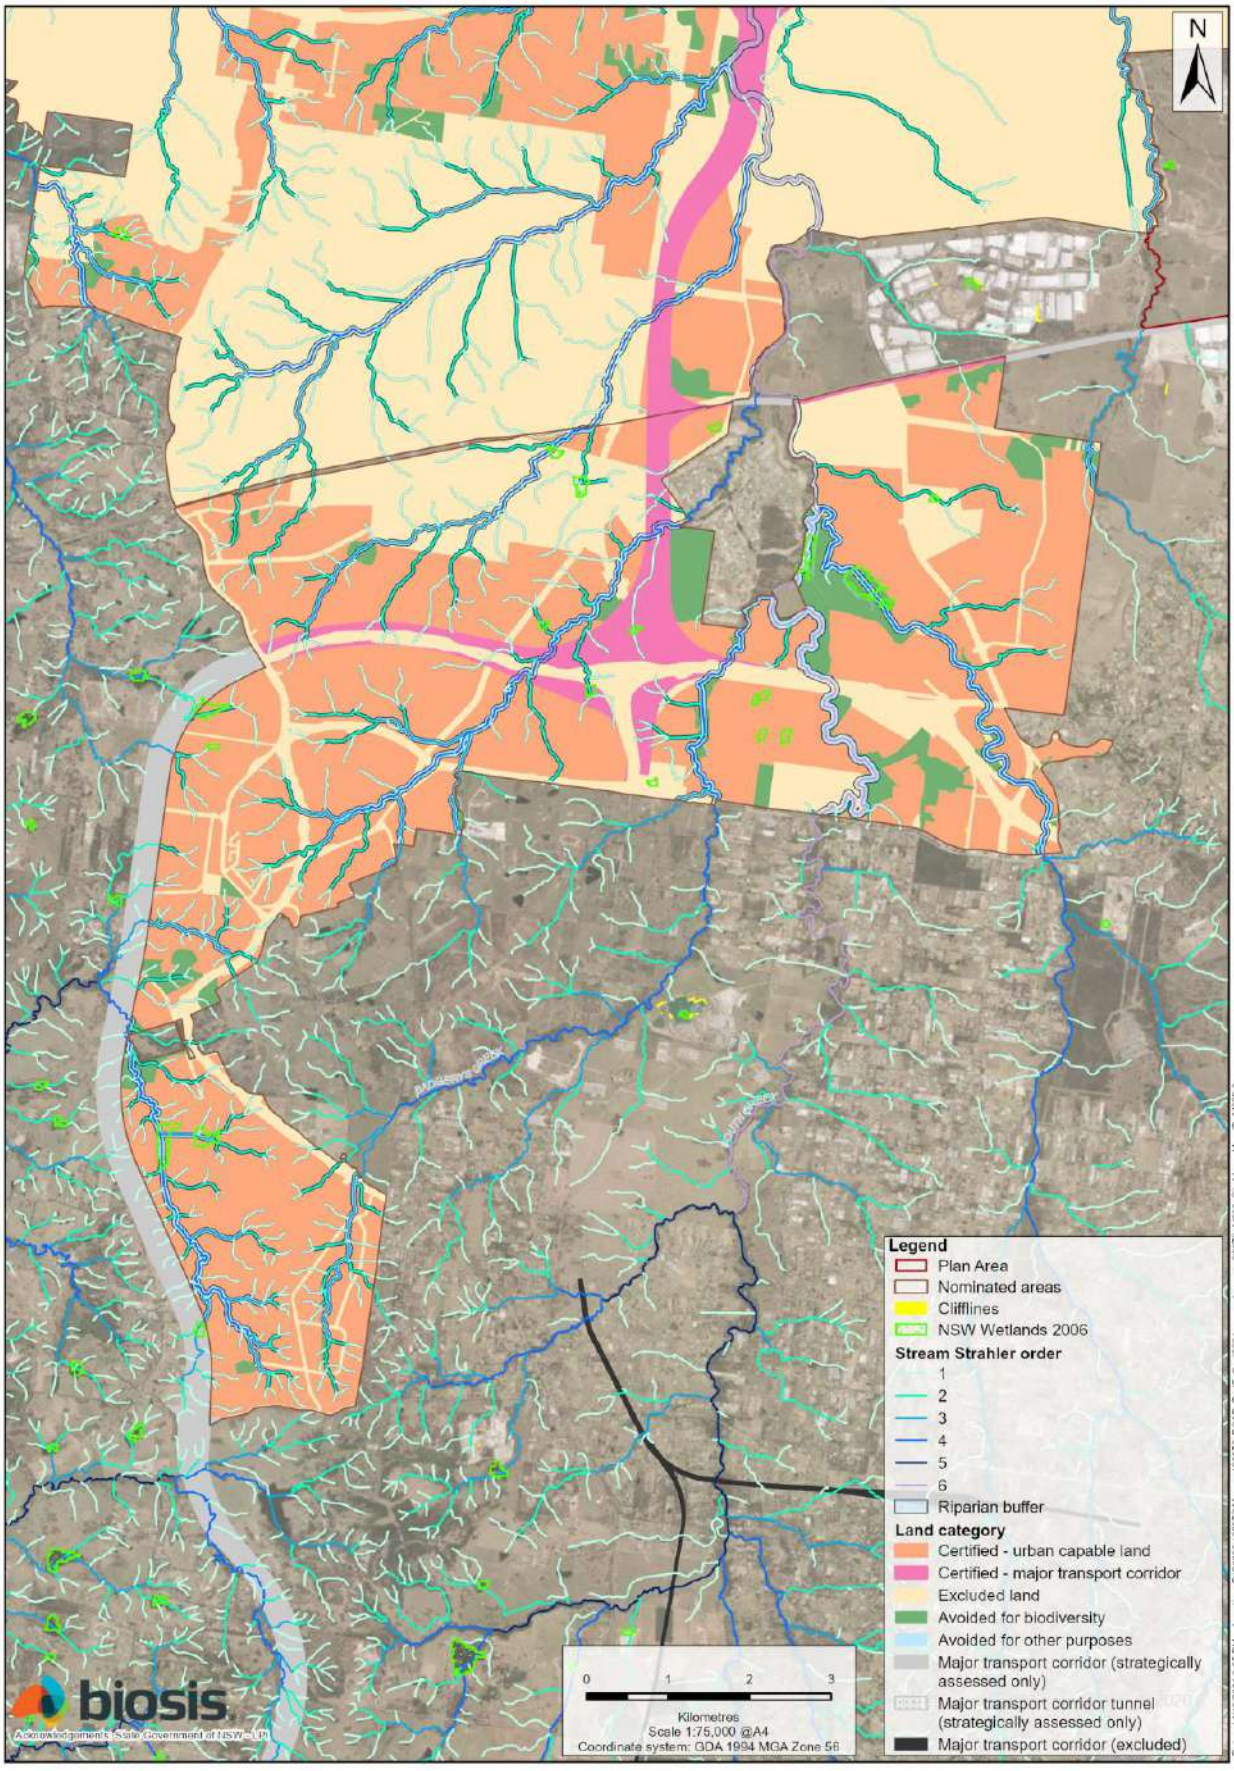

Figure 18-3: Site map – WSA

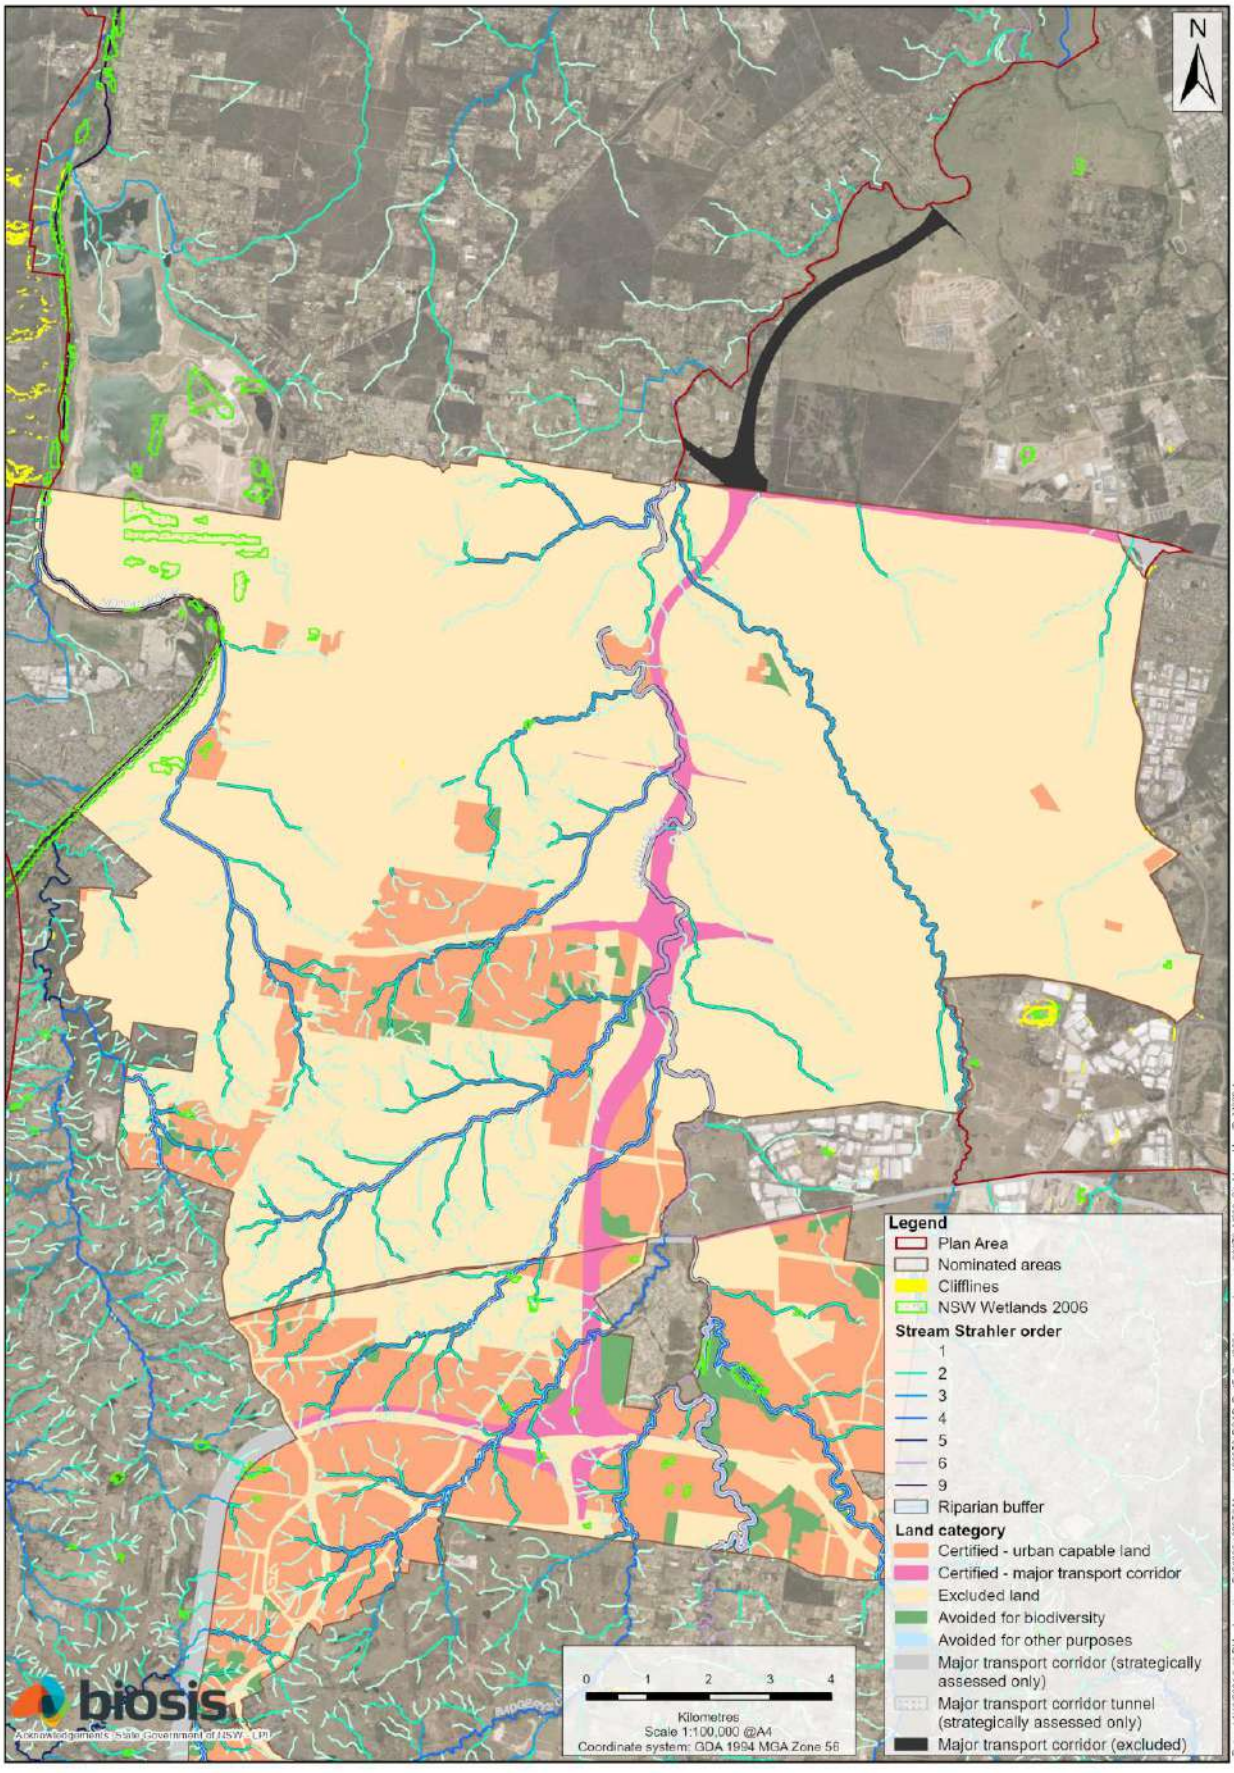

Figure 18-4: Site map – GPEC

18.2 NATIVE VEGETATION EXTENT – BUFFER AREA

Table 18-2 provides the percentage cover of native woody and derived grassland vegetation within the urban capable land of each nominated area, and the 1,500 m buffer. The vegetation mapping within the 1,500 m buffer was undertaken using existing vegetation mapping only, therefore the native vegetation extent for derived grasslands is likely to be under-represented.

Table 18-2: Native vegetation cover

Nominated area	Native vegetation extent (ha) (%)	Native vegetation extent (%) within urban capable land*		Native vegetation extent (%) within 1,500 m buffer*		
		Woody	Derived grasslands	Woody	Derived grasslands	Cover Class
Wilton	2,347 (58%)	9	28	46	6	>30-70%
GMAC	3,254 (30%)	9	3	33	1	>30-70%
WSA	876 (14%)	8	1	21	<1	>10-30%
GPEC	3,254 (17%)	8	2	20	<1	>10-30%

* Percentages rounded to whole numbers

18.3 NSW (MITCHELL) LANDSCAPES

NSW landscapes (also known as Mitchell Landscapes (Mitchell, 2002)) that occur within the nominated areas are described in Table 18-3. The landscape entered into the BAM calculator for each nominated area is the landscape in which most of the likely impacts within a nominated area occur and is marked with an asterisk in the table.

Table 18-3: NSW (Mitchell) landscapes

NSW (Mitchell) landscape	Subregion	Nominated area	Area of landscape in nominated area (ha)	Description
Upper Nepean Gorges	Cataract	Wilton	1,463	The Upper Nepean Gorges landscape is characterised by steep-sided benched slopes of the Nepean River tributaries on Triassic age quartz sandstones, with elevation of 250 to 350 m and local relief of 80 m. The landscape has shallow, well-drained sands with limited development of yellow texture-contrast soils on benches underlain by clayey sandstone of thin shale units
		GMAC	1,433	
Picton-Razorback Hills	Cumberland and Cataract	Wilton	2,499*	The Picton-Razorback Hills landscape is a plateau ridge with steep slopes on horizontal upper Triassic shale, carbonaceous claystone, and lithic sandstone, subject to extensive earthflows on slopes above 120 m. General elevation is 180 to 300 m with local relief of 90 m. Soils are harsh, red, brown, or yellow texture-contrast soils with reactive clay subsoils
		GMAC	3,127	
Cumberland Plain	Cumberland and Cataract	Wilton	109	The Cumberland Plain landscape is characterised by low, rolling hills and valleys in a rain shadow area between the Blue Mountains and the coast on horizontal Triassic shales and lithic sandstones forming a down-warped block on the coastal side of the Lapstone monocline. It is partly covered by Tertiary river gravels and sands (Hawkesbury-Nepean Terrace Gravels landscape). Quaternary alluvium occurs along the mains streams. General elevation is 30 to 120 m, with local relief of 50 m. The landscape is sometimes affected by dryland salinity in tributary valley floors. Soils are pedal uniform red to brown clays on volcanic hills, and red and brown texture-contrast soils on crests grading to yellow harsh texture-contrast soils in valleys
		GMAC	3,751*	
		WSA	5,285*	
		GPEC	14,522*	
Hawkesbury - Nepean Channels and Floodplains	Cumberland	GMAC	450	The Hawkesbury –Nepean Channels and Floodplains landscape is a meandering channel and moderately wide floodplain of the Hawkesbury and Nepean rivers on Quaternary sand and gravel. Sand is dominant upstream of the Warragamba River junction with general elevation 0 to 20 m and local relief of less than 10 m. Soils are characterised as undifferentiated alluvial sand to poorly structured gradation profiles of sandy loam or clay loam
		WSA	871	
		GPEC	3,347	
Woronora Plateau	Cataract and Cumberland	GMAC	354	The Woronora Plateau landscape is an extensive plateau developed on Triassic quartz sandstone with benched, low angle slopes and a marked break to steep sided, deep valleys controlled by joint patterns. General elevation is 400 to 500 m with local relief of 100 m. There are small areas of nodular ironstone on ridge crests, with deep uniform sands or texture-contrast soils on slopes and deep, uniform, grey or white organic sands on swampy valley floors. Rock outcrop is common on ridgelines and in creeks, and absent from most slopes

NSW (Mitchell) landscape	Subregion	Nominated area	Area of landscape in nominated area (ha)	Description
Ashfield Plains	Cumberland	GMAC	724	The Ashfield Plains landscape is a coastal extension of the Cumberland Plain landscape and is characterised by undulating hills and valleys on horizontal Triassic shale and siltstone, and occasional quartz sandstones, especially near the margin of the Port Jackson landscape. General elevation is 0 to 45 m with local relief of less than 20 m. Soils are red and brown texture-contrast on crests, grading to yellow harsh texture-contrast soils in valleys
Georges River Alluvial Plain	Cumberland	GMAC	1,107	Georges River Alluvial Plain comprises channel, floodplain, and terraces of the Georges River on Quaternary and Tertiary alluvial sediments. Mostly clayey sand and sand with limited gravel on the highest terrace, general elevation 0 to 30 m, local relief 10 m. Massive uniform or gradational profiles on yellow brown to orange clayey sand. Podzols with well-developed double pans on limited areas of deep quartz sand, stony, harsh, yellow, texture-contrast soils on higher terraces
Sydney Basin Diatremes	Cumberland	GMAC	12	Sydney Basin Diatremes are widely distributed across the Sydney Basin and distinguished as a landscape because they always contain locally different landform, soil, and vegetation. Diatremes are circular volcanic vents filled with layered, brecciated country rock cemented by a fine-grained basaltic matrix. Some contain a core of basalt. In sandstone country the volcanic breccia weathers and erodes more rapidly than the sandstone and the landform is circular with the appearance of a crater. Soils in the crater are dominated by sandstone detritus from the surrounding slopes but the subsoils are a fertile well, structured clay derived from the breccia and these protected sites carry more mesic variants of the local vegetation. In shale country the breccia is more resistant than the shale and the diatremes form a low rounded hill with red-brown gradational profiles of clay loam and structured clay with moderate to high fertility. General elevation varies considerably across the basin
		WSA	5	
		GPEC	28	
Hawkesbury - Nepean Terrace Gravels	Cumberland	GPEC	718	Hawkesbury - Nepean Terrace Gravels comprise three levels of river terrace dating into the Tertiary. General elevation is 20 to 45 m, local relief 10 m. Planar, poorly drained terraces with harsh texture-contrast soils and heavy clays in swamps and cut-off meanders
Kurrajong Fault Scarp	Cumberland	GPEC	3	Kurrajong Fault Scarp dissected and broken slopes on Triassic Quartz sandstone and shale across the Lapstone monocline and Kurrajong fault scarp. Local dips on the sedimentary rocks up to 300, general elevation 100 to 250 m, local relief 100 m. Abundant rock outcrop with pockets of yellow-brown sand and occasional yellow texture-contrast soils

*NSW (Mitchell) Landscape entered into the BAM calculator for each nominated area

18.4 RIVERS AND STREAMS

The nominated areas are located within two catchments (OEH, 2010):

- Hawkesbury
- Port Jackson/Georges River

Within the nominated areas, the watercourses and creeks provide riparian connectivity, and connections to the major watercourses of the Georges River (to the east) and the Hawkesbury-Nepean River (to the west).

Major watercourses of each nominated area are described in Table 18-4. Unnamed and minor tributaries are numerous throughout the nominated areas and are not listed in the tables.

Table 18-4: Watercourses of the nominated areas

Nominated areas	General Information	Major watercourses	Watercourse Strahler order*
Wilton	Wilton is located at the southern end of the Cumberland subregion. Four major watercourses run through the area, which generally have a south to north flow regime. There are several creeks that junction into the major watercourses	Nepean River, flowing west then north of Wilton	The Strahler order of the watercourses across Wilton is as follows: • One seventh-order watercourse • Three fourth-order watercourses • Six third-order watercourses • 26 second-order watercourses • 110 first order watercourses
		Allen's Creek, starting just south-east of Wilton, flowing north into the Nepean River	
		Other smaller creeks include Sand Gully Creek, a second-order tributary as well as Clements Creek, a third order tributary	
		Stringybark Creek, a third-order tributary situated downstream of Clements Creek	
GMAC	GMAC stretches from Glenfield to Appin. There are three major watercourses that have a south to north flow regime	Bow Bowing Creek, a major watercourse that runs north-east through northern GMAC The creek has several lower-order tributaries associated with it including Smith's Creek, McBarron Creek, Leumeah Creek, Fishers Ghost Creek, Birunji Creek, and Keanes Creek Georges River is generally east of GMAC	The Strahler order of the watercourses across GMAC is as follows: • Three seventh-order watercourses • Four sixth-order watercourses • One fifth-order watercourse • 11 fourth-order watercourses • 16 third-order watercourses • 68 second-order watercourses • 245 first-order watercourses
		Nepean River borders the south-west portion of GMAC, it is the major watercourse flowing south to north There are four creeks that converge into the Nepean River that run through the southern portion of GMAC: • Menangle Creek, a fourth-order tributary, flowing west • Leafs Gully Creek, a second-order tributary, flowing north-west	

Nominated areas	General Information	Major watercourses	Watercourse Strahler order*
		• Ousedale Creek, a fourth-order tributary flowing north west • Simpsons Creek, a third-order tributary, flowing north-west into the Nepean River	
		The Cataract River forms the southern border of GMAC Rocky Ponds Creek, a third-order tributary, converges into Cataract River	
WSA	The WSA contains five major watercourses. All watercourses have several tributaries	Ropes Creek forms the eastern border of WSA, it is a perennial creek, flowing northwards. Wianamatta (South Creek) which also flows northwards has four high-order tributaries (some listed below) and two third-order creeks that junction into it. Badgerys Creek is a fourth-order watercourse that has several unnamed tributaries	The Strahler order of the watercourses across the WSA is as follows: • One sixth-order watercourse • Four fourth-order water courses • 15 third-order watercourses. • 59 second-order watercourses • 208 first-order watercourses
		Kemps Creek, flows in a north-west direction, it is a perennial creek that converges into Wianamatta (South Creek). Kemps Creek has three unnamed tributaries that come from an easterly direction	
		Cosgroves Creek flows through WSA in a north-east direction. It has several creeks and tributaries that converge with it, including Oaky Creek	
		Duncans Creek drains the south-west corner of WSA and junctions into the Nepean River in the west	
GPEC	The GPEC has three major watercourses. There are several creeks that junction into these major watercourses	Nepean River forms the western border for GPEC, flowing from south to north Four creeks flow into the Nepean River: • Boundary Creek, a second-order tributary with a westerly flow • Peach Tree Creek, a fourth-order tributary with a northern flow • Surveyors Creek, which junctions just north of the western motorway School House Creek is the most southern creek to junction into the Nepean River	The Strahler order of the watercourses across GPEC is as follows: • One ninth-order watercourse • Two sixth-order watercourses • Seven fourth-order water courses • 15 third-order watercourses • 53 second-order watercourses

Nominated areas	General Information	Major watercourses	Watercourse Strahler order*
		Ropes Creek, runs through GPEC and is a major watercourse	• 193 first-order watercourses
		Wianamatta (South Creek) flows south to north through the middle of GPEC. It has several smaller tributaries that feed into the large watercourse including: • Werrington Creek • Claremont Creek • Blaxland Creek • Byrnes Creek	
		Kemps Creek, flows in a north-west direction, it is a perennial creek that converges into Wianamatta (South Creek). Kemps Creek has three unnamed tributaries that come from an easterly direction	
		Cosgroves Creek flows through WSA in a north-east direction. It has several creeks and tributaries that converge with it, including Oaky Creek	
		Duncans Creek drains the south-west corner of WSA and junctions into the Nepean River in the west	

* This stream order system was originally developed by Strahler (1964). It functions by adding two streams of equal order at their confluence to form a higher order stream. As stream order increases, so does the likelihood that it would be a perennial source of water

18.5 WETLANDS

There are no wetlands protected under the Coastal Management State Environmental Planning Policy (SEPP) within the nominated areas. These wetlands were previously listed as SEPP 14 – Coastal Wetlands.

Locally occurring wetlands that provide wetland habitats include areas of floodplain wetland along the Nepean River, Wianamatta (South Creek) and Werrington Creek, farm dams and reservoirs. There are more than 60 of these types of wetland habitats mapped across the nominated areas (OEH, 2011a).

There are no nationally important wetlands or Ramsar-listed wetlands within the nominated areas. The closest nationally important wetlands to the nominated areas are (DoEE, 2018):

- Towra Point (Ramsar site) 25 kilometres east of Glenfield
- Lake Illawarra, 30 kilometres to the south-east of Wilton
- Bicentennial Park, Newington Wetlands, Silverwater Nature Reserve, 17 kilometres east of Prospect Reservoir
- Pitt Town Lagoon, Pitt Town
- Longneck Lagoon, Pitt Town

The closest Ramsar wetland is located at the Towra Point Nature Reserve, in Botany Bay.

18.6 HABITAT CONNECTIVITY AND FRAGMENTATION

The soils of the Cumberland subregion are relatively fertile, particularly when compared to the surrounding Hawkesbury Sandstone landscapes. This fertility has resulted in extensive clearing of native vegetation for agriculture, market gardens and orchards. More recently, clearing has occurred for urban development.

Only approximately 13 per cent of the pre-1970 extent of native vegetation in the Cumberland subregion remains intact and in good condition, with an additional 12 per cent occurring as scattered trees in disturbed areas (DECCW, 2011).

Remaining native vegetation is often highly fragmented. In 2010, an estimated 2,446 individual native vegetation remnants remained in the subregion, ranging from less than 1 hectare to 3,598 hectares in area (DECCW, 2010). Eighty one of the largest patches (those greater than 50 hectares) represent 51 per cent of the remaining native vegetation (DECCW, 2011).

Fragmentation of habitats across and between the nominated areas mirrors this general pattern of clearing and development in the Cumberland subregion, with significant areas of native vegetation community restricted to reserves, major riparian corridors, sandstone geologies and areas not suited to agriculture, such as steep slopes and escarpments.

The impacts of the development on habitat connectivity are assessed in Chapter 24.

18.6.1 WILTON

Connectivity of intact vegetation within Wilton is generally in the hilly, gorge and riparian corridors on the fringes of the nominated area. There is intact vegetation creating connectivity along Allens Creek from the west of the nominated area towards the areas of more intact vegetation south of the nominated area. Habitat for native species within the central parts of the nominated area (predominantly on shale soils) is restricted to scattered trees and derived grasslands or small native remnants of less than 5 hectares, which are under pressure from weed invasion, edge impacts and ongoing agricultural practices.

Map 24-3 shows habitat connectivity within Wilton.

18.6.2 GMAC

Fragmentation of habitat within GMAC is also typical of that seen in the Cumberland subregion, with clearing of vegetation from the fertile crests, and the low-lying and alluvial soils. However, due to the presence of riparian corridors and sandstone geologies there is some connectivity of intact habitats along a number of east-west corridors in the southern portion of GMAC. These connections reach from the Nepean River riparian corridor on the western boundary, to near the eastern boundary, where the habitats of the Georges River riparian corridor are located.

Habitat connectivity within the highly developed northern portion of the nominated area is restricted to small local connections such as largely cleared riparian corridors and urban bushland parks. Scattered trees and urban native vegetation are also present in this area, providing some connectivity for highly mobile species.

Map 24-3 shows habitat connectivity within GMAC.

18.6.3 WSA

WSA is characterised predominantly by an agricultural landscape with limited small acreage subdivision in the far south and larger acreage and small residential subdivisions in the centre and northern parts. Some small acreage subdivisions contain native vegetation, providing local connections for native fauna and flora species.

Other native vegetation habitats are present along the many riparian corridors that cross WSA, including Wianamatta (South Creek), Duncans Creek and Badgerys Creek corridors and tributaries. There are remnant patches of vegetation located between Willowdene Avenue and the Northern Road in the central part of the nominated area around Duncans Creek, providing some limited connectivity east-west. There are also many waterbodies within WSA that provide habitat connectivity for species dependent on these environments for dispersal and reproduction.

Map 24-3 shows habitat connectivity within WSA.

18.6.4 GPEC

GPEC has been extensively developed for housing. Intact native vegetation and habitats are restricted to the far north of the nominated area around the Wianamatta Regional Park, and the Orchard Hills Defence Establishment in the far south of the nominated area. These two areas of remnant habitats are connected via the riparian corridors of Wianamatta (South Creek). The Ropes Creek corridor reaches from the Wianamatta Regional Park through to the south-east of the nominated area. Both of these major riparian corridors have been subject to varying levels of clearing and disturbance. However, they provide the only vegetated link within the local and regional landscape for native flora and fauna species.

Map 24-3 shows habitat connectivity within GPEC.

18.7 AREAS OF GEOLOGICAL SIGNIFICANCE AND SOIL HAZARDS

Areas of geological significance occur outside urban capable land on the edges of some of the nominated areas, including rocky escarpments associated with surrounding sandstone landscapes. These areas may be important for species that have specific habitat constraints and associations. Areas of potential soil hazard within the nominated areas include:

- Acid Sulfate Soils
- Sodic soils
- Salinity
- Land contamination
- Soil compaction
- Unstable soils

The impacts of the development on karst, caves, crevices and cliffs are assessed in Chapter 24.

18.7.1 ACID SULFATE SOILS

Table 18-5 provides a description of the soil hazard map units identified in the Atlas of Australian Acid Sulfate Soils (Fitzpatrick, Powell et al., 2011).

Areas of high probability Acid Sulfate Soils within the nominated areas are shown in Map 18-5.

Table 18-5: Acid Sulfate Soils within the nominated areas

Map Units	Probability of occurrence	Map unit	Subscript	Confidence	Nominated area
Bn(p4)	B - Low (6-70%)	n - Inland landscapes in wet/riparian corridors associated with sodosols, chromosols and dermosols. Acid Sulfate Soils generally within upper 1 m of wet / riparian corridors	p - Potential acid sulfate soil (PASS) = sulfidic material	4- Classification is provisional	GMAC GPEC
Cq(p4)	C- Extremely low (1-5%)	q - Inland landscapes in wet/riparian corridors associated with kandosols, tenosols and rudosols. Acid Sulfate Soils generally within 1 m	p - Potential acid sulfate soil (PASS) = sulfidic material	4- Classification is provisional	Wilton GMAC WSA GPEC

Map Units	Probability of occurrence	Map unit	Subscript	Confidence	Nominated area
		of wet/riparian corridor			
Cu(--)	C- Extremely low (1-5%)	u - unclassified Not Acid Sulfate Soils	Not Acid Sulfate Soils	Not Acid Sulfate Soils	GMAC GPEC
An(p4)	A - High (>70%)	n - Inland landscapes in wet/riparian corridors associated with sodosols, chromosols and dermosols. Acid Sulfate Soils generally within upper 1 m of wet / riparian corridors	p - Potential Acid Sulfate Soil (PASS) = sulfidic material	4- Classification is provisional	WSA GPEC
Aq(p4)	A - High (>70%)	q - Inland landscapes in wet/riparian corridors associated with kandosols, tenosols and rudosols. Acid Sulfate Soils generally within 1 m of wet/riparian corridor	p - Potential acid sulfate soil (PASS) = sulfidic material	4- Classification is provisional	WSA GPEC
Cn(p4)	C- Extremely low (1-5%)	n - Inland landscapes in wet/riparian corridors associated with sodosols, chromosols and dermosols. Acid Sulfate Soils generally within upper 1 m of wet / riparian corridors	p - Potential Acid Sulfate Soil (PASS) = sulfidic material	4- Classification is provisional	WSA GPEC

18.7.2 SODIC SOILS

Sodicity refers to the proportion of exchangeable sodium cations held on the surface of clay particles. The greater the proportion of sodium in the total exchangeable cations, the greater the sodicity of the soil.

Sodic soils cause clay dispersion, an undesirable condition.

Sodic soils could occur within the nominated areas, most likely in riparian corridors and near dams. A site assessment would be necessary to determine extent at specific locations.

18.7.3 SALINITY

Salinity refers to the amount of dissolved salt in the soil. A large concentration of salt gives high salinity and increasing salinity makes it difficult for plant roots to absorb water.

The Western Sydney Hydrogeological Landscape maps show the majority of Western Sydney as having high land salinity. Wilton is mapped as having low to moderate land salinity, while parts of the assessment area north of Wilton are predominantly high land salinity areas (OEH, 2011b).

Site assessments would be required to determine the salinity of individual sites.

18.7.4 LAND CONTAMINATION

Land contamination can threaten human health and the environment, limit land use potential or increase development costs. Contaminated sites are typically found in areas that have been used for heavy industry or agriculture, chemical storage areas and service stations and dry cleaning sites (NSW EPA, 2019).

Declarations of significantly contaminated lands have been made for various sites across each of the nominated areas, primarily relating to industrial sites. The list of current declarations for each Local Government Area (LGA) within the nominated areas is available through the NSW Environment Protection Authority website.

18.7.5 SOIL COMPACTION

Compaction of soils can occur through movement of stock, machinery, or vehicles. When soil becomes compacted, air and water movement through the soil are restricted, limiting their use.

Compacted soils within the nominated areas are most likely to be found in areas used for grazing or agriculture. Areas of susceptibility are likely to occur on the alluvial plains and the Cumberland Plain Mitchell Landscape.

Site assessments would be required to determine soil compaction levels at individual sites.

18.7.6 UNSTABLE SOILS

Unstable soils are referred to as 'dispersible soils' and are often associated with high levels of salt. They are vulnerable to compaction, surface sealing and erosion. Areas of potential high land salinity within the nominated areas are more likely to exhibit unstable soils. Potential areas of instability and potential for gully erosion within the nominated areas are most likely to occur in areas of high slope, salinity, and reduced vegetation ground cover.

Within the nominated areas, the Wianamatta (South Creek) soil landscape has high to extreme potential for erosion, and stream bank and gully erosion in this landscape can result from concentrated water flows. The Luddenham Soil Landscape has a moderate to very high potential for erosion, with minor gully erosion and sheet erosion in disturbed areas.

18.8 AREAS OF OUTSTANDING BIODIVERSITY VALUE

No areas identified as Areas of Outstanding Biodiversity Value occur within the nominated areas (OEH, 2020).

18.9 SITE CONTEXT

This section describes the site context, in accordance with section 4.3 of the BAM, for each of the nominated areas.

18.9.1 PER CENT NATIVE VEGETATION COVER

Per cent native vegetation cover is shown in Table 18-6 for the:

- Nominated areas
- Urban capable land
- 1,500 m buffer areas

Table 18-6: Native vegetation cover

Nominated area	Native vegetation cover (%)	Cover Class	Native vegetation cover (%) – urban capable land*	Cover Class	Native vegetation cover (%) – 1,500 m buffer*	Cover Class
Wilton	58	>30-70%	37	>30-70%	52	>30-70%
GMAC	30	>10-30%	12	>10-30%	34	>30-70%
WSA	14	>10-30%	9	0-10%	21	>10-30%
GPEC	17	>10-30%	10	0-10%	20	>10-30%
Average	30	>10-30%	17	>10-30%	32	>30-70%

* Percentages rounded to whole numbers

18.9.2 CHANGES TO THE MAPPED NATIVE VEGETATION EXTENT

Several areas of native vegetation shown on the existing native vegetation maps (OEH, 2013, 2016) have been cleared since the maps were prepared and no longer exist. These areas were discernible on Nearmap aerial imagery (Nearmap, 2018) and were excluded from the updated vegetation maps. Areas of urban vegetation such as roadside plantings were also excluded. These areas were ground-truthed during surveys where possible to positively identify them as being non-native vegetation or native vegetation with a cultivated origin.

18.9.3 PATCH SIZE

Patch size for BAM credit calculations was defined as greater than 100 hectares for all vegetation zones in the nominated areas. This served to not limit the potential threatened species that could be recorded or identified in the assessment for consideration.

19 Native vegetation

This Chapter describes the native vegetation communities in the nominated areas, including vegetation extent, PCTs and vegetation condition (native vegetation integrity).

The method for identifying and mapping native vegetation within the nominated areas is provided in Chapter 11.

19.1 NATIVE VEGETATION EXTENT

The total extent of vegetation within the nominated areas is 11,764 hectares (see Table 19-3). This includes:

- 9,730 ha of native vegetation, including areas with native dominated ground cover and canopy area of trees
- 2,034 ha of 'Urban Native/Exotic' vegetation, which comprises areas of exotic vegetation or with few native species, as well as planted vegetation, landscaped areas, gardens, and other areas that are not considered representative of 'native vegetation' and/or a PCT

Map 19-1 shows the extent of native vegetation within the nominated areas, including the extent of the 'Urban Native/Exotic' vegetation.

19.2 PLANT COMMUNITY TYPES

A total of 15 different PCTs occur within the nominated areas. In addition to these 15 PCTs, a category of vegetation called 'Urban Native/Exotic' vegetation also occurs (see Table 19-1).

A description of the PCTs that occur within the nominated areas, including the percentage of each PCT that has been cleared (up to 2018) (OEH, 2018) is provided in Table 19-1.

Table 19-2 provides a justification for the identification of each PCT in accordance with section 5.2.1.12 of the BAM which included:

- Qualitative analysis of BAM plot data (including photographs) against BioNet (PCT ID tools) using filters such as the; Sydney Basin IBRA, Sydney Cataract and Cumberland IBRA Subregions, vegetation class and formation, vegetation description followed by analysis of upper, mid and ground stratum floristics, identified dominant strata species followed
- Matching the outputs of the quantitative analysis of the BAM plot survey data to PCTs followed by cross referencing of the identified PCT against available vegetation mapping for the region to verify and confirm
- Quality checking of PCT analysis through entering all BAM plot data into 'Tozer tool' floristic assessment worksheets to confirm PCT suitably based on the presence of positive diagnostic species for Tozer et al (2010) map units, to the 95% confidence interval, where sufficient data existed
- Final mapping of the PCTs

Table 19-3 provides the amount (hectares) of each PCT within the nominated areas.

The five most extensive PCTs (including the Urban Native/Exotic category of vegetation) within the nominated areas are:

- 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest – 3,357 ha
- 849 Grey Box - Forest Red Gum grassy woodland on flats – 2,890 ha
- Urban Native/Exotic – 2,034 ha
- 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats – 1,187 ha
- 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes – 774 ha

Map 19-2, Map 19-3, Map 19-4 and Map 19-5 show the distribution of PCTs within the nominated areas.

Table 19-1: PCTs within the nominated areas

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (BioNet)
724	Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forest	Cumberland Dry Sclerophyll Forest	This community is associated with shale-influenced sandy soils that support a component of ironstone gravels. The vegetation typically consists of an open eucalypt forest with an understorey that varies between dense shrubs and a low sparse shrub cover with an abundant ground cover of grasses. The canopy typically includes Broad-leaved Ironbark *Eucalyptus fibrosa* along with a wide variety of other eucalypts depending on location. White Feather Honeymyrtle *Melaleuca decora* is sometimes present above a lower open shrub layer of Blackthorn *Bursaria spinosa* and Gorse Bitter Pea *Daviesia ulicifolia*. The ground cover is a mix of grasses, sedges, and herbs. On the basis of floristic composition alone, Castlereagh Shale-Gravel Transition Forest is closely related to Castlereagh Ironbark Forest	75%
725	Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forest (Shrub/grass sub-formation)	Cumberland Dry Sclerophyll Forest	This community is associated with clay soils derived from Tertiary alluvial deposits (Tozer 2003). It is one of two closely related ironbark shrub-grass forests found in western Sydney. The structure ranges from a moderately tall open eucalypt forest or woodland to a low dense thicket of paperbarks with low emergent eucalypts. Human-induced changes to the original forest structure have resulted in the presence of varying structures of the community Benson and Howell (1994a). Broad-leaved Ironbark is the most commonly recorded eucalypt although at some sites it may be absent Woollybutt *Eucalyptus longifolia* is also common although sites often have a diverse canopy composition which reflects subtle grades between substrates sourced from Tertiary sand, sandstone bedrock, shale, and ironstone gravels. For this reason, there are localised occurrences of Hard-leaved Scribbly Gum *Eucalyptus sclerophylla*, Smooth-barked Apple *Angophora costata* and Narrow-leaved Apple *Angophora bakeri*, species more typically associated with siliceous soils of sand deposits and the sandstone plateau. A prominent small tree layer of White Feather Honeymyrtle features above a dense cover of shrubs that include *Melaleuca nodosa*, Blackthorn and Peach Heath *Lissanthe strigosa* The ground layer is a sparse cover of grasses and forbs. These may be very depauperate in locations where dense shrub layers exclude light	95%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (BioNet)
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Freshwater Wetlands	Coastal Freshwater Lagoons	This community is associated with freshwater lagoons and swamps on alluvial flats and sand depressions across the NSW east coast. Lagoons have fluctuating levels of standing water that gives rise to a varied assemblage of species. They include a range of sedges, rushes and aquatic herbs with woody shrubs and small trees found only on the margins of the wetlands in low abundance. Tall reedlands (reaching over 3 m in height) may dominate individual wetlands. Cumbungi *Typha orientalis* is typically dominant in urban wetlands and may be joined by Common Reed *Phragmites australis*. Other tall reeds include *Eleocharis sphacelata* and tall sedges such as Twig-rushes *Baumea* spp. The margins of open water carry a range of aquatic herbs such as *Isachne gibbosa* and *Persicaria decipiens*. Less frequently inundated wetlands support only a few species of sedges or rushes such as *Carex appressa* and *Baumea* spp. which do not reach the height of the taller reedlands found elsewhere	74%
830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community occurs on protected aspects on steeper shale hills and rises of the southern half of the Cumberland Plain. It differs from the grassy woodlands found in Western Sydney by the prevalence of waxy-leaved shrubs and small trees in the understorey and a ground cover of herbs, fleshy twiners and grasses. Some of these species, such as Hairy Clerodendrum *Clerodendrum tomentosum* and Slender Grape *Cayratia clematidea*, are features of the Hinterland Dry Rainforest, a community that occasionally occurs in more protected situations nearby. Across its range in Western Sydney the canopy is mostly dominated by Forest Red Gum *Eucalyptus tereticornis* and Grey Box *Eucalyptus moluccana*. Much of this habitat has been extensively cleared, with remaining stands commonly choked by dense thickets of African Olive *Olea europaea* subsp. *cuspidata* and Lantana *Lantana camara*. This reduces species diversity and in chronic situations it may be difficult to correctly diagnose the community due to low numbers of native species	75%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (BioNet)
835	Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Forested Wetlands	Coastal Floodplain Wetlands	This community is located on broad alluvial flats of the Hawkesbury and Nepean river systems. It also forms narrower ribbons alongside streams and creeks that drain the Cumberland Plain. The canopy typically includes one of either Rough-barked Apple *Angophora floribunda* or Broad-leaved Apple *Angophora subvelutina* and one or both of Forest Red Gum and Cabbage Gum *Eucalyptus amplifolia*. However, eucalypt species will vary between localities, including Blue Box *Eucalyptus baueriana*, Sydney Blue Gum *Eucalyptus saligna* and Blackbutt *Eucalyptus pilularis*. The understorey within this community is characterised by an occasional sparse to open small tree stratum of Paper Bark *Melaleuca* spp. and Wattles *Acacia* spp. A sparse lower shrub layer features Blackthorn *Bursaria spinosa* at most sites. The ground layer is characterised by an abundant cover of grasses with herbs and ferns	93%
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community is one of two grassy woodlands that comprise Cumberland Plain Woodland listed under the BC Act. The community includes an open grassy woodland dominated by Grey Box, Forest Red Gum and Narrow-leaved Ironbark and Broad-leaved Ironbark. Like the related community Cumberland Shale Hills Woodland, it is typified by a sparse to moderate cover of shrubs and a high cover of grasses and forbs	93%
850	Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community is one of two grassy woodlands that comprise the Cumberland Plain Woodland listed under the BC Act. The community is an open woodland of Grey Box and Forest Red Gum with Narrow-leaved Ironbark also common. Hickory Wattle *Acacia implexa* occurs amongst the small tree layer, often amongst regrowth stands. This species is one of the more distinctive floristic attributes that helps distinguish between the two components of the EEC. Other features are similar in that the two woodland units are characterised by an open shrub layer and a grassy ground cover. Fire history can have an important influence on the abundance of shrubs (Watson et al. 2009), with density of Blackthorn *Bursaria spinosa* increasing with time since fire	88%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (BioNet)
877	Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion	Rainforests	Dry Rainforests	This community occurs on very sheltered clay-rich soils of the undulating hills and ranges of western Sydney and the southern Blue Mountains. Grey myrtle *Backhousia myrtifolia* is the most common and abundant rainforest species. Other locally prominent species include fig *Ficus rubiginosa*, wild quince *Alectryon subcinereus* and whalebone tree *Streblus brunonianus*. The rainforest canopy may include eucalypts (in the study area spotted gum *Corymbia maculata* is common), wattles and paperbarks. The former is more commonly an emergent layer and the latter prevalent in hillside drainage lines. Several mesic shrubs consistently occur including hairy clerodendrum *Clerodendrum tomentosum* and large mock olive *Notelaea longifolia*. The ground cover is a sparse cover of herbs and ferns.	25%
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forests (Shrubby sub-formation)	Sydney Sand Flats Dry Sclerophyll Forests	This community is one of several unique dry shrub woodland communities found on poorly consolidated sand deposits on hinterland plains and valleys of the Sydney region. The woodland comprises an open, low-growing eucalypt cover dominated by Hard-leaved Scribbly Gum *Eucalyptus sclerophylla*, Narrow-leaved Apple and Drooping Red Gum *Eucalyptus parramattensis* subsp. *parramattensis*. A sparse cover of White Feather Honeymyrtle is often present. Banksias, hakeas, wattles, tea-trees and paperbarks provide a well-developed shrub layer. The ground cover is usually a diverse mix of species typically including a high cover of grasses and sedges	50%
1081	Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forests (Shrubby sub-formation)	Sydney Hinterland Dry Sclerophyll Forests	This community is equivalent to DSF 146 identified by Tindall et al. (2004) and is a eucalypt woodland with an open understorey of sclerophyll shrubs, sedges, forbs and grasses. This transition woodland encircles the Cumberland Plain rainshadow, on loamy soils typically derived from sediments belonging to the Hawkesbury or Mittagong formations. 40 per cent of this community's original distribution has been cleared and clearing continues in localised areas of suburban expansion. However, considerable areas are represented within conservation reserves	40%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (BioNet)
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Forested Wetlands	Eastern Riverine Forests	Open *Casuarina* forest, 10-40 m tall, with a variable non-sclerophyll shrub stratum and patchy groundcover of sedges and herbs, interspersed with leaf litter, cobbles and open sand. Restricted to narrow bands along rivers of the coast and tablelands north from Bega continuing into central Queensland	40%
1181	Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Dry Sclerophyll Forests (Shrubby sub-formation)	Sydney Coastal Dry Sclerophyll Forests	This community is equivalent to DSF 142 identified by Tindall et al. (2004) and is an open eucalypt forest with an abundant sclerophyll shrub stratum and a groundcover dominated by sedges. This community grades from Hinterland Sandstone Gully Forest into Sandstone Riparian Scrub immediately adjacent to creeklines and is replaced by Coastal Sandstone Ridgetop Woodland or Wingecarribee-Burragorang Sandstone Forest on upper slopes and exposed positions. Dominant trees include; Smooth-barked Apple, Red Bloodwood *Corymbia gummifera*, Sydney Peppermint *Eucalyptus piperita*. As rainfall increases toward the coast, it is replaced by Coastal Sandstone Gully Forest. Much of this community's original distribution has been cleared. Large areas remain, including examples in conservation reserves, though edge effects such as weed invasion and high fire frequency are evident in some locations	20%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (BioNet)
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	Forested Wetlands	Eastern Riverine Forests	This low scrub comprises a mix of hardy shrubs growing on rocky creek lines or shallow alluvial soils at the base of deep sandstone gully systems. The vegetation cover is highly variable as it is interspersed by rock pools, rock pavements and open sandy banks. It is a zone of occasional flooding and plants must survive fast-moving waters to persist. Water gums *Tristaniopsis laurina* and *Tristania neriifolia* are invariably present, often in combination with wattles, hakeas, grevilleas, tea-trees and casuarinas. Two shrub species, River Lomatia *Lomatia myricoides* and Blunt-leaved Wattle *Acacia obtusifolia*, are particularly common in this community; both are easily distinguished by their long leaves. Small moisture-loving ferns and sedges may form dense clumps on or near stream banks. A sparse cover of overhanging eucalypts may also be present, though these are often rooted in the adjoining slopes rather than the creek line itself	10%
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community is found on the fringes of the Cumberland Plain. It is one of a suite of forests that are associated with the subtle intergrade between clay-rich shale soil and the coarse sandy substrates of the sandstone plateau. It is a moderately tall eucalypt forest with a mixed understorey of sclerophyll shrubs and grasses (Tozer et al. 2010). Sites invariably have one of two species of Ironbark, Narrow-leaved Ironbark and Broad-leaved Ironbark, present in the canopy along with Grey Gum *Eucalyptus punctata* and Red Bloodwood. A sparse cover of tall Casuarinas *Allocasuarina littoralis*/*Allocasuarina torulosa* is common. The understorey supports a mix of shrubs that are common on shale substrates such as Blackthorn *Bursaria spinosa* and those more commonly associated with sandstone soils such as Geebungs (*Persoonia* spp). Beneath this diverse mix of shrubs is a high cover of grass and forbs. The grass layer includes a wide range of species, most of which occur more extensively on the Cumberland Plain	80%
1800	Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley	Forested Wetlands	Coastal Floodplain Wetlands	This community is found on the river flats of the Cumberland Plain in western Sydney. The distinguishing feature is the prominent stands of Swamp Oak *Casuarina glauca* found along or near streams. Often these are relatively young trees, swarming amongst a mix of old and young eucalypts such as Rough-barked Apple *Angophora floribunda*, Forest Red Gum and Grey Box. This community features an open grassy and herbaceous understorey, as is typical of river flat forests	60%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (BioNet)
	Urban Native/Exotic			Vegetation that is not consistent with floristic composition and landscape positions for native plant community types as defined by the NSW BioNet Vegetation Classification system; most commonly communities comprise of very few native species or consist of an assorted mix of planted natives	

*Adapted from the BioNet Vegetation Information System (VIS) database

Table 19-2: Justification for the identification of PCTs

PCT	Name	Diagnostic species present in BAM plot data (as aligned with BioNet PCT descriptions)	Additional justification of evidence to identify the PCT (Source: BioNet and BAM plot data)
724	Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	*E. fibrosa, M. decora, Lissanthe strigosa, Microlaena stipoides* var. *stipoides, Cheilanthes sieberi, Lobelia purpurascens, Wahlenbergia gracilis, Aristida vagans, Lomandra multiflora*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion, Dry Sclerophyll Forests (Shrub/grass sub-formation) and match with BAM plot upper, mid, and ground strata diagnostic species Associated with shale-gravelly soils. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open eucalypt forest with an understorey that may vary between dense shrubs and a low sparse shrub cover with an abundant ground cover of grasses, sedges, and herbs, consistent with the species assemblage for this PCT
725	Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	*E. fibrosa, M. decora, M. nodosa, Bursaria spinosa, Daviesia ulicifolia, Lobelia purpurascens, Microlaena stipoides* var. *stipoides, Pomax umbellata, Ozothamnus diosmifolius, Lepidosperma laterale, Laxmannia gracilis*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion, Dry Sclerophyll Forests (Shrub/grass sub-formation) and match with BAM plot upper, mid, and ground strata diagnostic species Associated with clay soils derived from Tertiary alluvial deposits and laterized deeply weathered shale. This PCT was found in varying degrees of condition and species composition. In intact condition, the structure ranges from a moderately tall open eucalypt forest or woodland to a low dense thicket of paperbarks with low emergent eucalypts, consistent with the species assemblage for this PCT
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	*Typha orientalis, Phragmites australis, Eleocharis sphacelata, Carex appressa, Baumea juncea, Baumea* spp. and *Persicaria strigosa*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion, Freshwater Wetlands and match with BAM plot upper, mid and ground strata diagnostic species Associated with freshwater lagoons and swamps on alluvial flats, found generally at low elevations less than 20 m above sea level, and up to 50 m above sea level. This PCT was found in varying degrees of condition and species composition. In intact condition, the lagoons consist of a range of sedges, rushes and aquatic herbs

PCT	Name	Diagnostic species present in BAM plot data (as aligned with BioNet PCT descriptions)	Additional justification of evidence to identify the PCT (Source: BioNet and BAM plot data)
			with woody shrubs and small trees, consistent with the species assemblage for this PCT
830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*E. tereticornis, E. moluccana, Clerodendrum tomentosum, Solanum prinophyllum, Microlaena stipoides* var. *stipoides*	Sydney Basin IBRA, Cumberland Subregion, Grassy Woodlands and match with BAM plot upper, mid and ground strata diagnostic species Associated with protected aspects on steeper shale hills and rises of the southern half of the Cumberland Plain. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open grassy woodland with prevalence of waxy-leaved shrubs and small trees in the understorey and a ground cover of herbs, fleshy twiners, and grasses, consistent with the species assemblage for this PCT
835	Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	*E. tereticornis, Angophora floribunda, E. amplifolia* subsp. *amplifolia, Acacia parramattensis, Bursaria spinosa* subsp. *spinosa, Microlaena stipoides* var. *stipoides, Dichondra repens, Solanum prinophyllum, Commelina cyanea, Lobelia purpurascens, Veronica plebeia*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Forested Wetlands and match with BAM plot upper, mid, and ground strata diagnostic species Associated with broad alluvial flats, streams, and creeks at altitudes between one and 160 m above sea level. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open eucalypt forest, with occasional sparse to open small tree stratum and a sparse lower shrub layer, with an abundant cover of grasses, small herbs, and ferns, consistent with the species assemblage for this PCT
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	*E. moluccana, E. tereticornis, Bursaria spinosa* subsp. *Spinosa, Cheilanthes sieberi* subsp. *Sieberi, Aristida vagans, Aristida ramosa, Euchiton sphaericus, Microlaena stipoides* var. *stipoides, Lomandra filiformis, Goodenia hederacea, Dichelachne micrantha, Themeda triandra*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Grassy Woodlands and match with BAM plot upper, mid, and ground strata diagnostic species Associated with gentle topography generally at less than 150 m above sea level and can occur over 300 m above sea level in some locations. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open grassy eucalypt woodland with a sparse to moderate cover of shrubs and a high cover of grasses and forbs, consistent with the species assemblage for this PCT
850	Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*E. moluccana, E. tereticornis, Bursaria spinosa* subsp. *spinosa, Dichondra repens, Microlaena stipoides* var. *stipoides, Carex*	Sydney Basin IBRA, Cumberland Subregion Grassy Woodlands and match with BAM plot upper, mid, and ground strata diagnostic species Associated with elevations between 50 m and 350 m above sea level in more rugged landforms separating this from gentler landforms occupied by PCT 849.

PCT	Name	Diagnostic species present in BAM plot data (as aligned with BioNet PCT descriptions)	Additional justification of evidence to identify the PCT (Source: BioNet and BAM plot data)
		inversa, Asperula conferta, Oxalis perennans, Wahlenbergia gracilis	This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open woodland with an open shrub layer and a grassy ground cover, consistent with the species assemblage for this PCT
877	Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion	No BAM plot data, PCT not impacted	Sydney Basin IBRA, Cumberland Subregion Rainforests and match with BAM plot upper, mid, and ground strata diagnostic species This PCT typically occurs as a simple, low closed forest with a sparse groundcover. It is widely distributed as small patches throughout the dry gorge country of the southern Blue Mountains (Coxs, Kowmung and Wollondilly gorges), the margins of the Cumberland Plain, and the Shoalhaven and Ettrema Gorges. It usually occupies the steep lower slopes of gorges below 600m ASL with an annual rainfall from 750 - 900mm, where pre-Permian rocks underlying those of the Sydney Basin are exposed (Tozer et al 2010) Within the nominated areas it occurs at one location in Greater Macarthur where it was confirmed as present during public submission and mapping received as prepared by a BAM Accredited ecological consultant. Access to the vegetation was not possible during the project's field campaign and as such no detailed vegetation community assessment was undertaken or plot data was collected.
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	*E. sclerophylla, M. decora, M nodosa, Grevillea mucronulata, Cyathochaeta diandra, Lomandra multiflora, Cheilanthes sieberi; Dianella revoluta*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Dry Sclerophyll Forests (Shrubby sub-formation) and match with BAM plot upper, mid, and ground strata diagnostic species Associated with soils derived from Tertiary alluvium, or on sites located on adjoining shale or Holocene alluvium, with sandy deposits. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as a shrubby woodland with an open, low-growing eucalypt cover, well developed shrub layer, and a diverse mix of species typically including a high cover of grasses and sedges, consistent with the species assemblage for this PCT
1081	Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion	*E. punctata, Entolasia stricta, Persoonia linearis, Leptospermum trinervium, Acacia ulicifolia, Lambertia formosa, Dianella revoluta* var. *revoluta*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Dry Sclerophyll Forests (Shrubby sub-formation) and match with BAM plot upper, mid, and ground strata diagnostic species This community is present on loamy soils on dry ridges in the rainshadow zone surrounding the Cumberland Plain. It occurs at elevations below 400 m above sea level. This PCT was predominantly found in moderate condition, with an intact

PCT	Name	Diagnostic species present in BAM plot data (as aligned with BioNet PCT descriptions)	Additional justification of evidence to identify the PCT (Source: BioNet and BAM plot data)
			native canopy over ground and midstorey layers subject to weed incurrence. The species composition was consistent with the species assemblage for this PCT and Proteaceae (particularly banksias) are often present
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	*Casuarina cunninghamiana, Acacia floribunda, Lomandra longifolia, Microlaena stipoides* var. *stipoides*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Forested Wetlands and match with BAM plot upper, mid, and ground strata diagnostic species Associated with sand or gravel alluvium along rivers and streams between 1 m and 600 m. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open or tall open forest with an open shrub layer and a dense or patchy groundcover of grasses and forbs, consistent with the species assemblage for this PCT
1181	Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	*Corymbia gummifera, E. pilularis, Banksia spinulosa, Allocasuarina littoralis, Dianella caerulea, Lomandra longifolia, Pomax umbellata, Xanthorrhoea arborea, Entolasia stricta, Phyllanthus hirtellus*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Dry Sclerophyll Forests (Shrubby sub-formation) and match with BAM plot upper, mid, and ground strata diagnostic species Associated with lower slopes of dry sandstone gullies up to 600 m above sea level. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open eucalypt forest with an abundant sclerophyll shrub stratum and a groundcover dominated by sedges, consistent with the species assemblage for this PCT
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	Only 1 BAM plot undertaken, community not being impacted. *Backhousia myrtifolia, Morinda jasminoides, Pittosporum undulatum, Wahlenbergia gracilis*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Forested Wetlands The BAM plot floristics are not a great match, however the landscape position i.e. proximity to the Nepean River, and broader community structure aligned PCT 1292 as the best fit throughout the nominated areas This community is present on sandy banks and sandstone beds of streams draining sandstone plateaux below 450 m elevation. It was mainly present in good condition within the Plan Area, with a species composition and structure that aligns with the descriptive characteristics for the PCT
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	*E. crebra, Allocasuarina littoralis, E. fibrosa, E. punctata, Bursaria spinosa* subsp. *spinosa, Entolasia stricta, Dichondra repens, Microlaena*	Sydney Basin IBRA, Sydney Cataract and Cumberland Subregion Grassy Woodlands and match with BAM plot upper, mid and ground strata diagnostic species

PCT	Name	Diagnostic species present in BAM plot data (as aligned with BioNet PCT descriptions)	Additional justification of evidence to identify the PCT (Source: BioNet and BAM plot data)
		stipoides var. *stipoides, Cheilanthes sieberi, Themeda australis*	Associated with clay-rich shale soil and the coarse sandy substrates of sandstone plateaus. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as a moderately tall eucalypt forest with a mixed understorey of sclerophyll shrubs and grasses, consistent with the species assemblage for this PCT. Generally with few to no Proteaceae present, which distinguishes the community from PCT 1081
1800	Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley	*Casuarina glauca, E. tereticornis* and *E. moluccana, M. styphelioides, Bursaria spinosa, Casuarina glauca, Acacia decurrens, Dichondra repens, Commelina cyanea, Lobelia purpurascens*	Sydney Basin IBRA, Cumberland Subregion Forested Wetlands and match with BAM plot upper, mid and ground strata diagnostic species Associated with grey-black clay-loams and sandy loams, on drainage lines, lake margins and estuarine fringes associated with coastal floodplains, generally below 20 m elevation but up to 60 m ASL in the upper Wianamatta (South Creek) reaches. This PCT was found in varying degrees of condition and species composition. In intact condition it occurs as an open grassy and herbaceous understorey, consistent with the species assemblage for this PCT
	Urban Native/Exotic	Exotic species	This PCT is associated with exotic species, and the species assemblage was not associated with a PCT

*All plot data were entered into the BioNet PCT ID tool and the Tozer vegetation identification tool and then reviewed by ecologists with experience in the vegetation of the Cumberland Plain

19.3 NATIVE VEGETATION CONDITION

Vegetation zones have been identified within the nominated areas in accordance with the method described in Chapter 11. A vegetation zone is an area of native vegetation that is the same PCT and has a similar condition state.

There is a total of 44 vegetation zones within the nominated areas.

Table 19-4 identifies the area of each native vegetation zone within each nominated area. A description of the vegetation condition categories shown in Table 10 is provided in Chapter 11.Table 19-5 identifies the area of Non-Offsettable Grassland (NOG) in the nominated areas.

The current vegetation integrity score (a measure of vegetation condition) of each vegetation zone within the nominated areas is provided in Table 19-6. The vegetation integrity score has not been calculated for each nominated area separately as the nominated areas comprise a single biodiversity certification area over which all plots were collected.

Map 19-6, Map 19-7, Map 19-8, and Map 19-9 show the vegetation zones within each nominated area.

Table 19-4: Vegetation condition and amount (ha) of each PCT and condition type within the nominated areas

*Vegetation integrity scores are only calculated for zones impacted by the proposed development. Of the 44 zones in the nominated areas, 31 are impacted

20 Threatened ecological communities

A total of nine NSW-listed TECs occur within the nominated areas.

The method to determine the TECs that occur within the nominated areas is explained in Chapter 11.

Identification of the NSW-listed TECs that occur within the nominated areas, as well as the extent of each TEC within each nominated area, is provided in Table 20-1.

Table 20-1 also indicates whether a PCT is notionally associated with a Commonwealth-listed TEC. It is important to note that Commonwealth-listed TECs often do not align exactly to a PCT and are usually defined differently to NSW-listed TECs. Commonwealth-listed TECs are described and assessed in Chapter 31.

The five most extensive NSW TECs within the nominated areas are:

- Cumberland Plain Woodland – 3,358 ha (this comprises 2,890 ha of PCT 849, and 468 ha of PCT 850)
- Shale Sandstone Transition Forest – 3,357 ha
- River-flat Eucalypt Forest on Coastal Floodplains – 1,187 ha
- Shale Gravel Transition Forest – 296 ha
- Swamp Oak Floodplain Forest – 227 ha

Map 20-1, Map 20-2, Map 20-3, and Map 20-4 show the distribution of TECs within each nominated area.

Table 20-1: TECs and amount (ha) of each TEC within the nominated areas

21 Threatened species and habitat

This Chapter identifies the NSW-listed ecosystem credit species (ECS) and candidate species credit species (SCS) predicted to occur within the nominated areas and provides maps of the locations of the habitat for candidate SCS.

The method to predict the ECS and SCS within the nominated areas is explained in Chapter 9.

21.1 ECOSYSTEM CREDIT SPECIES

The ECS predicted to occur within the nominated areas are provided in Table 21-1.

The method to predict the ECS within the nominated areas is explained in Chapter 11.

A total of 46 ECS are predicted to occur within the nominated areas.

For this assessment, it was assumed that all ECS predicted to occur within the nominated areas are present, and no ECS were excluded from the assessment as allowed under section 6.4 of the BAM.

Table 21-1: Ecosystem credit species predicted to occur within the nominated areas

Scientific name	Common Name	NSW status^	Cth status^	Habitat constraints	Sensitivity to gain class	Predicted location

*These species are ECS in relation to foraging habitat only

21.1.1 SPECIES CREDIT SPECIES

Section 6.4 of the BAM sets out a process for determining the SCS that need to be assessed in the Assessment Report. The method to predict the candidate SCS within the nominated areas is explained in Chapter 11.

Table 21-2 identifies the list of SCS predicted to occur according to the BAM calculator, and:

- The nominated area that the SCS is predicted to occur within (marked with a tick or cross)
- Whether the SCS has been removed from needing further assessment within a nominated area (marked with an 'R')
- The remaining list of candidate SCS
- The method used to determine the presence of each candidate SCS

Attachment A in Chapter 11 provides a justification for each SCS removed from needing further assessment and identifies the relevant section of the BAM under which a SCS was removed. Section 6.1.1.2 of the BAM was the primary basis used for removing a SCS from needing further assessment.

A total of 83 SCS were predicted to occur within the nominated areas.

Of these, 41 SCS were determined to be candidate SCS needing further assessment, and 42 were removed.

Table 21-3 identifies the amount of habitat for each candidate SCS in the nominated areas.

The following maps show the distribution of habitat within the nominated areas for each candidate SCS:

- Map 21-1– *Acacia bynoeana*
- Map 21-2– *Acacia pubescens*

CUMBERLAND PLAIN ASSESSMENT REPORT

PART 5B: BCAR STAGE 2 (IMPACT ASSESSMENT)

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

DOCUMENT TRACKING

PREPARED BY:	
DATA:	James Shepherd, Callan Wharfe, Rebecca Dwyer, Matthew Hyde (Biosis)
CONTENT:	Callan Wharfe, Rebecca Dwyer (Biosis) Darren James (DAJ Environmental) Tom Holden, Stephanie Binks, Natasha Buckingham, Heidi Birkby, Christa Shen, Peter Hemphill, Heather Tolley (Open Lines)
REVIEWED BY:	
OPEN LINES:	Darren James (DAJ Environmental) Tom Holden, Peter Hemphill (Open Lines)
ACCREDITED ASSESSOR:	Jane Raithby-Veall (Biosis) BAM Assessor (BAAS18134)
VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 5B Contents

Part 5B List of Tables

22 Introduction

This Part provides an assessment of the impacts of the urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors under the Plan within the nominated areas for matters listed under the BC Act in accordance with the BAM, including:

- Direct impacts on Plant Community Types (PCTs), threatened ecological communities (TECs), and threatened species and habitat (Chapter 23)
- Prescribed impacts (Chapter 24)
- Serious and irreversible impacts (SAII) (Chapter 25)
- Impact summary, including the number of credits that would be required to be retired to offset the impacts (Chapter 26)

Direct impacts described in Chapter 23 are identified in terms of:

- Impacts of urban, industrial, infrastructure, and intensive plant agriculture development within each nominated area and total impacts across all nominated areas
- Total impacts of the transport development across all nominated areas
- Total impacts of the urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors across all nominated areas

Note that the only development types in Wilton Growth Area (Wilton) are urban, industrial and infrastructure development.

Avoidance and minimisation of impacts on biodiversity values is described in Chapter 14.

Indirect impacts on native vegetation and habitat are described in Chapter 15.

23 Direct impacts on native vegetation and habitat

23.1 APPROACH TO THE ASSESSMENT

The BAM defines in detail the method for addressing direct impacts. In summary, this involved:

- Assessing the direct impacts that will result from the clearing of native vegetation, TECs and threatened species habitat (Section 9.1.2 of the BAM)
- Calculating:
  - The change in vegetation integrity for each vegetation zone and species polygon (Section 9.1.3 of the BAM)
  - The required number of ecosystem credits for direct impacts (Section 11.2.3 of the BAM)
  - The required number of species credits for direct impacts (Section 11.2.4 of the BAM)
- Identifying the credit class for ecosystem credits and species credit (Section 11.3 of the BAM)

23.2 NATIVE VEGETATION

23.2.1 VEGETATION ZONES

Table 23-1 summarises the amount (hectares) of each vegetation zone that will be directly impacted within the nominated areas, including:

- Urban and industrial development, infrastructure, and intensive plant agriculture within urban capable land
- Major transport corridors
- Total impacts from development under the Plan

A total of 1,753.6 ha of native vegetation occurs within the urban capable land and major transport corridors and will be impacted by the development under the Plan. The five most impacted vegetation zones (excluding non-offsettable grassland) are:

- PCT 849_Thinned – 301.7 ha
- PCT 849_DNG – 227.4 ha
- PCT 1395_DNG – 227.5 ha
- PCT 850_DNG – 195.2 ha
- PCT 835_Thinned – 150.0 ha

Table 23-1: Direct impacts on vegetation zones within each nominated area

1800_Scattered_trees	1800	Scattered trees	0.0	0.0	1.4	0.0	0.1	**1.6**	No
Total			**628.8**	**344.2**	**342.6**	**161.9**	**276.1**	**1,753.6**	

^ While hollow-bearing trees may not have been recorded within plots used to assess that vegetation zone, they may occur elsewhere within the vegetation zone

* Totals highlighted in blue are based on raw vegetation data outputs. Some rounding errors may occur between the impact areas quoted for each nominated area and the summed total for each vegetation zone.

23.2.2 NON-OFFSETTABLE GRASSLAND

Table 23-2 provides a summary of impacts to non-offsettable grassland vegetation types within the nominated areas.

Non-offsettable grassland comprises grassland vegetation zones with a vegetation integrity score of <15 and does not require offsetting for the associated PCT under the BAM. However, where non-offsettable grasslands support species credit species habitat, offsets may be required for those species.

Table 23-2: Direct impacts on non-offsettable grassland (NOG) within the nominated areas

Vegetation zone			Area (ha) impacted					
Vegetation zone ID	PCT	Condition	Wilton	GMAC	WSA	GPEC	Major transport corridors	Total*
835_NOG	835	NOG	0.0	21.1	648.9	313.4	217.8	**1,201.3**
849_NOG	849	NOG	676.5	1,341.1	2,380.2	622.1	323.2	**5,343.1**
850_NOG	850	NOG	12.3	454.2	10.0	228.4	0.0	**704.9**
1395_NOG	1395	NOG	322.3	471.2	0.0	0.0	0.0	**793.5**

* Totals highlighted in blue are based on raw vegetation data outputs. Some rounding errors may occur between the impact areas quoted for each nominated area and the summed total for each vegetation zone.

23.2.3 VEGETATION INTEGRITY

Table 23-3 shows the change in vegetation integrity as a result of the urban and industrial development, infrastructure, intensive plant agriculture and major transport corridors within the nominated areas. Change in vegetation integrity is a measure of the direct impact on native vegetation and species habitat.

It has been assumed that all vegetation will be removed within the urban capable land of each nominated area and within the major transport corridors and therefore the future vegetation integrity score will be zero.

In practice some native vegetation will likely be retained through Development Control Plans and other planning processes and mechanisms, including hollow-bearing trees (see Chapter 15).

Table 23-3: Change in vegetation integrity due to urban and industrial development, infrastructure, intensive plant agriculture and major transport corridors

Vegetation zone			Area (ha) impacted	Current vegetation integrity score before development	Future vegetation integrity score after development	Change in vegetation integrity score

23.3 THREATENED ECOLOGICAL COMMUNITIES

Table 23-4 summarises the amount (hectares) of each TEC that will be directly impacted within the nominated areas, including:

- Urban and industrial development, infrastructure, and intensive plant agriculture within urban capable land
- Major transport corridors
- Total impacts from development under the Plan

A total of 1,753.6 ha of TECs occurs within the urban capable land and major transport corridors and will be impacted by the development under the Plan. The TEC mapping method used is generally conservative and is more likely to over-predict distribution of TECs. Limitations to the mapping are further discussed in Chapter 13.3.

The five most impacted TECs are:

- Cumberland Plain Woodland – 931.5 ha
- Shale Sandstone Transition Forest – 459.8 ha
- River-flat Eucalypt Forest on Coastal Floodplains – 185.9 ha
- Shale Gravel Transition Forest – 108.3 ha
- Cooks River/Castlereagh Ironbark Forest – 37.6 ha

23.4 THREATENED SPECIES AND SPECIES HABITAT

Table 23-5 identifies the amount of habitat (in hectares) of each candidate species credit species (SCS) that will be directly impacted within the nominated areas, including:

- Urban and industrial development, infrastructure, and intensive plant agriculture within urban capable land
- Major transport corridors
- Total impacts from development under the Plan

The five SCS with the largest area of potential habitat impacted by development under the Plan are:

- *Acacia pubescens* – 1,321.4 ha
- *Pimelea spicata* – 870.4 ha
- *Myotis macropus* – 759.2 ha
- *Meridolum corneovirens* – 720.1 ha
- *Grevillea juniperina* subsp. *juniperina* – 467.5 ha

It is important to note that the knowledge-based method used to determine habitat for some species is based on assuming presence within areas of potential habitat. The method is therefore likely to greatly overestimate the amount of actual or known habitat for these species impacted by the development (see Chapter 11).

The BAM requires certain candidate SCS to be assessed by a count of the species individuals directly impacted, rather than the area of habitat. One candidate SCS, *Epacris purpurascens* var. *purpurascens* requires assessment by a count of individuals. As the KBM process is limited to modelling habitat based on area, a modelled count of individuals is not possible. To address this for *Epacris purpurascens* var. *purpurascens* the following process was used to derive a biodiversity credit requirement for impacts to the species:

- All BioNet records of the species that occur within 20 kms of modelled habitat were selected to allow for consideration of populations in the locality of the nominated areas. Records used were sourced from "As Held BioNet Data" (at May 2021). A total of 314 records were considered, once duplicates had been removed
- To group individual records into populations, and to provide an estimated area within which the record occurs, each BioNet record was buffered by 56.42 m (radius) to create 1 ha buffers surrounding each point
- Buffer areas were then combined (with overlapping areas dissolved) to ascertain an area value for each group of records. A total of 108 buffer areas (populations) were created, ranging in area from 1 ha to 6.7 ha
- BioNet records were interrogated to determine the number of individual plants each record represents. Where no counts were provided the number of individuals was assumed to be one. Numbers of individuals per BioNet record ranged from 1 to 25,000. When these were provided as a range, the mid-point of the range was used
- The total individuals present within each buffer area (based on all BioNet records within each buffer area) were then summed to determine the number of individuals per population. The total individuals per population was divided by the total area of the buffer to ascertain the individuals per hectare estimate
- Individuals per hectare values were ranked and the median value of 8 individuals per hectare was selected. The median value is considered to be more suitable than the mean to return the central tendency for a skewed number distribution such as this dataset. The data ranges from 1 individual per hectare to 27,500 individuals per hectare, with 94 of the 108 total entries returning less than 1,000 individuals per hectare

Note that Little Eagle and Square-tailed Kite are candidate SCS for breeding habitat only. Expert reports were prepared for these species that mapped areas of 'breeding and foraging habitat' (equating to potential breeding habitat) within Wilton and GMAC. An additional 1,322.98 ha of foraging habitat for Little Eagle and 510.84 ha of foraging habitat for Square-tailed Kite were mapped within the expert reports which have not been included in the candidate SCS calculations, as they are not considered to be impacts to the species as required by the BAM and include mainly grassed paddocks. Potential breeding habitat is generally restricted to heavily vegetated areas outside urban capable land, however there is considerable overlap between potential forage habitat and urban capable land. In addition, impacts of 0.80 ha to a buffer around a confirmed stick nest (species not known) in GPEC, associated with grassed paddocks commensurate with the habitat mapped as potential forage habitat by the expert in Wilton and GMAC, has also been excluded from the candidate SCS calculations.

*These species are SCS in relation to breeding habitat or mapped "important habitat" only

+7.7 hectares of impact to Green and Golden Bell Frog is associated with vegetation removal and hence has been entered into the BAM Calculator to determine the resultant credit requirement. The remaining 5.6 hectares of impact is associated with man-made structures and has been assessed under Prescribed Impact in Section 16.3 of the BCAR

++ 26.0 hectares of impact to Swift Parrot important habitat is associated with vegetation removal and hence has been entered into the BAM Calculator to determine the resultant credit requirement. The remaining 17.3 hectares of impact is associated with waterbodies and Non-Native Vegetation and has been assessed under Prescribed Impact in Section 16.3 of the BCAR

+++72.9 hectares of impact to *Hibbertia fumana* and 76.9 hectares of impact to *Hibbertia puberula* is associated with vegetation removal and hence has been entered into the BAM Calculator to determine the resultant credit requirement. The remaining 1.1 hectare of impact (for each species) is associated with Non-Native Vegetation and has been assessed under Prescribed Impact in Section 16.3 of the BCAR

#862.36 hectares of impact to *Pimelea spicata* is associated with vegetation removal and hence has been entered into the BAM Calculator to determine the resultant credit requirement. The remaining 8.1 hectares of impact is associated with Non-Native Vegetation and has been assessed under Prescribed Impact in Section 16.3 of the BCAR

~ Totals highlighted in blue are based on raw habitat data outputs. Some rounding errors may occur between the impact areas quoted for each nominated area and the summed total for each species

24 Prescribed biodiversity impacts

24.1 INTRODUCTION

The BAM requires prescribed impacts to be identified and assessed.

This Chapter sets out:

- Definition of prescribed impacts
- Approach taken to assessing prescribed impacts
- Identification of relevant prescribed impacts
- Presence and abundance of species and TECs associated with each prescribed impact type
- Assessment of the impacts of the urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors within the nominated areas under the Plan in relation to each relevant prescribed impact

24.2 DEFINITION OF PRESCRIBED IMPACTS

Prescribed impacts can be defined generally as impacts on biodiversity values that do not comprise direct clearing of native vegetation that are assessed through credits. Prescribed impacts comprise impacts on (Clause 6.1, BC Regulation):

- Habitat features for threatened species or TECs:
  - Karst, caves, crevices, cliffs, and other geological features of significance
  - Rocks
  - Human-made structures
  - Non-native vegetation
- Connectivity of habitat of threatened species that facilitates the movement of those species across their range
- Movement of threatened species that maintains their lifecycle
- Water quality, water bodies and hydrological processes that sustain threatened species and TECs
- Wind turbine strikes on protected fauna
- Vehicle strikes on threatened fauna or fauna that is part of a TEC

This assessment considered prescribed impacts to include two types:

- Prescribed impacts that are direct impacts. This includes, for example, direct removal of species habitat that is not native vegetation, such as rocks, water bodies or non-native vegetation
- Prescribed impacts that are indirect impacts. This includes, for example, indirect impacts on species habitat that is a water body through urban run-off, or indirect impacts to species through the severing of a habitat corridor

The assessment in this Chapter is considered in terms of both direct and indirect prescribed impacts.

24.3 APPROACH TO THE ASSESSMENT

The BAM requires the BCAR to identify and assess prescribed impacts within the nominated areas.

Section 6.7 of the BAM requires the BCAR to:

- Identify occurrences of habitats associated with prescribed impacts
- List the candidate SCS or ecosystem credit species (ECS) or TECs associated with those habitats
- Undertake targeted surveys for any relevant candidate SCS

Section 9.1.1.2 and 9. 2 of the BAM requires the BCAR to:

- Describe the nature, extent, frequency, duration, and timing of prescribed impacts relevant to the proposed development, including impacts during construction and operation

- Evaluate the consequences of prescribed impacts

The steps taken to assess prescribed impacts involved:

Step 1: Identify the relevant species and TECs (including ECS and candidate SCS) associated with each prescribed impact type within the nominated areas. This was done by drawing on ecological and life history information in BioNet profiles, as well as species records, habitat maps, and surveys undertaken for this assessment.

The following was described for each species or TEC:

- Likely presence/abundance of species/TEC in the nominated areas
- Use and importance of the prescribed impact type for the TEC/species

Step 2: Map the occurrence of each prescribed impact type within the nominated areas where possible. Where mapping was not possible (human-made structures, vehicle strikes) or not necessary (rock outcrops – see Section 24.7), the occurrence of the prescribed impact type in each nominated area was described and assessed qualitatively.

Mapping was undertaken for:

- Karst, caves, crevices, cliffs, and other geological features of significance
- Non-native vegetation
- Habitat connectivity and movement
- Water bodies and hydrological processes

The mapping of each prescribed impact type was overlayed on the urban capable land within each nominated area to provide impact data and other information on the nature, extent, and duration of impacts

Step 3: Describe the nature, extent, and duration of each prescribed impact type:

- Nature of impacts – qualitatively describe any direct impacts (e.g. removal or destruction of habitat) or indirect impacts (e.g. reduction in habitat connectivity, human use/disturbance, urban run-off)
- Extent of impacts – quantify the direct impacts where possible (e.g. the amount of habitat removed or destroyed (ha)) or the general location and extent of indirect impacts
- Duration – identify whether the impacts are permanent or temporary

Step 4: Describe the general mitigation measures and processes that will be implemented to mitigate prescribed impacts

Step 5: Assess the potential prescribed impacts on each TEC and species and identify any potential residual impacts. This was done taking into account:

- Likely presence/abundance of species/TEC and importance of the location at a local and regional scale
- Life history traits and susceptibility of the species/TEC to the prescribed impact
- Location of the species/TEC relative to the likely extent of the prescribed impact
- Amount and quality of unimpacted habitat remaining
- Levels of existing protection
- The effectiveness of the general mitigation measures and processes described through step 4

Step 6: Describe any additional specific mitigation measures needed to address potential residual prescribed impacts identified through step 4 to particular TECs or species

24.4 RELEVANT PRESCRIBED IMPACTS

The following prescribed impact types are relevant to the development:

- Karst, caves, crevices, cliffs, and other geological features of significance
- Rocks
- Human-made structures

- Non-native vegetation
- Habitat connectivity and movement
- Water bodies and hydrological processes
- Vehicle strikes

Prescribed impacts may be associated with direct or indirect impacts. Table 24-1 sets out the potential types of impacts associated with each prescribed impact type that are relevant to the development.

The prescribed impact type 'wind turbine strikes on protected fauna' is not relevant to the development and has not been considered further in this Assessment Report.

Table 24-1: Types of impacts associated with each prescribed impact type

Prescribed impact type	Associated potential direct impacts	Associated potential indirect impacts
Karst, caves, crevices, cliffs	Removal or destruction (e.g. cracking or collapse) of habitat	Recreational use/disturbance Noise or light disturbance
Rocks	Removal of habitat (rocks)	
Human-made structures	Removal of habitat (structures)	Human disturbance Noise or light disturbance
Non-native vegetation	Removal of habitat (non-native vegetation)	Recreational use/disturbance Weed invasion Spread of plant/animal disease Pest animals/predation/competition Soil erosion/sedimentation Urban run-off (water quality)
Habitat connectivity/movement	N/A	Reduction in habitat connectivity
Water bodies/hydrological processes	Removal of habitat (water bodies)	Change in water flows/quantity Urban run-off (water quality)
Vehicle strikes	Death of species individuals	N/A

24.5 PRESENCE/ABUNDANCE OF RELEVANT SPECIES

Table 24-2 identifies the presence and abundance of species and TECs associated with each prescribed impact type.

Note about Koala: development under the Plan within the nominated areas has the potential to impact the Southern Sydney Koala population. Impacts on Koala have been assessed in detail in Chapter 30, and impacts associated with prescribed impacts as defined in the BAM are summarised in this chapter.

Table 24-2: Relevant species/TECs potentially subject to prescribed impacts

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Plants			
Acacia bynoeana	Bynoe's Wattle	Records occur to the north of GPEC where there are a significant number of populations, and in Wilton in avoided/excluded lands	• Non-native vegetation
Grevillea juniperina subsp. *Juniperina*	Juniper-leaved Grevillea	Records occur in Western Sydney Aerotropolis (WSA) and Greater Penrith to Eastern Creek Investigation Area (GPEC). Most records for the species occur just north of GPEC. The species is	• Non-native vegetation

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
		known to occur in disturbed land at Marsden Park (Weston, 2019)	
Hibbertia fumana		Species is only known from the Moorebank and Bankstown areas outside the nominated areas. However, the species is recently described and if present, could have been recorded under a different name in previous studies	• Non-native vegetation
Hibbertia puberula		Records occur in the Plan Area, primarily near Holsworthy, with more sporadic records between Holsworthy and Campbelltown. There are also three records in Shanes Park close to the northern edge of GPEC. There are no records within the nominated areas	• Non-native vegetation
Persoonia bargoensis	Bargo Geebung	Records occur on the edge of Wilton within avoided/excluded lands. These records are part of a single population of the species that spans from Bargo to Picton in the north-west, through to Appin in the east	• Non-native vegetation
Pimelea spicata	Spiked Rice-flower	Records occur in GPEC and GMAC in avoided/excluded lands. Most records occur in the Blacktown, Prospect, Bankstown, and Narellan districts. One population in GMAC occurs within roadside vegetation within urban capable land	• Non-native vegetation
Bats			
Chalinolobus dwyeri	Large-eared Pied Bat	Records occur throughout the Cumberland subregion. Breeding habitat is associated with sandstone caves, crevices, and cliffs. Most records occur in the south of the subregion around Wilton. Interrogation of BioNet records suggests no roost sites occur in the nominated areas	• Karst, caves, crevices, and cliffs • Non-native vegetation • Habitat connectivity
Falsistrellus tasmaniensis	Eastern False Pipistrelle	Records occur within and surrounding the Cumberland subregion. Most records in the subregion occur in the eastern and northern parts. Few records occur in the nominated areas. The species has not been recorded in WSA	• Human-made structures • Non-native vegetation • Habitat connectivity
Miniopterus australis	Little Bent-winged Bat	Few records occur within the Cumberland subregion. The species has been recorded in three of the nominated areas (not WSA), including recently (< 5 years ago) in Wilton. Most records surrounding the subregion occur in coastal areas to the north	• Karst, caves, crevices, and cliffs • Human-made structures • Non-native vegetation • Habitat connectivity
Miniopterus orianae oceanensis	Large Bent-winged Bat	Records are widespread within and surrounding the Cumberland subregion. The species has been recorded in all four nominated areas, including recently (< 5 years ago)	• Karst, caves, crevices, and cliffs • Human-made structures • Non-native vegetation

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
			• Habitat connectivity
Micronomus norfolkensis	Eastern Coastal Free-tailed Bat	Records are widespread within and surrounding the Cumberland subregion. The species has been recorded in all four nominated areas, including recently (< 5 years ago) in Wilton and GPEC	• Human-made structures • Non-native vegetation • Habitat connectivity
Myotis macropus	Southern Myotis	Records are widespread within and surrounding the Cumberland subregion. The species has been recorded in all four nominated areas, including recently (< 5 years ago) particularly in Wilton and GPEC and just outside the northern part of GMAC. Suitable habitat has been mapped within each of the nominated areas. Suitable habitat occurs as scattered small to moderate size patches associated with native vegetation, including vegetation in low to moderate condition	• Human-made structures • Habitat connectivity • Water bodies
Pteropus poliocephalus	Grey-headed Flying-fox	The Plan Area supports significant numbers of the species across a number of camps. The location of breeding and roosting camps within the Cumberland subregion has been monitored since 2012 (Geoscience Australia, 2015). There are no known camps in the urban capable lands	• Non-native vegetation • Habitat connectivity
Saccolaimus flaviventris	Yellow-bellied Sheathtail-bat	Records occur within and surrounding the Cumberland subregion. Few records occur in the nominated areas. The species has not been recorded in WSA. Roost requirements are poorly known	• Human-made structures • Non-native vegetation • Habitat connectivity
Scoteanax rueppellii	Greater Broad-nosed Bat	Records occur within and surrounding the Cumberland subregion. Most records for the species in the subregion occur in the eastern part. Few records occur in the nominated areas	• Human-made structures • Non-native vegetation • Habitat connectivity
Marsupials			
Cercartetus nanus	Eastern Pygmy-possum	No records occur in the nominated areas. Records occur to the south and east of Wilton and east of GMAC outside the Cumberland subregion. Suitable habitat for the species is generally restricted to the gorges and gullies on the edges of Wilton, on the edges and through the middle of the southern part of GMAC, along riparian corridors in WSA and GPEC, and associated with larger patches of native vegetation within Wianamatta Regional Park and Orchard Hills	• Habitat connectivity • Vehicle strikes
Dasyurus maculatus	Spotted-tailed Quoll	Several important populations for the species have been identified within the vicinity of the nominated areas. Suitable habitat is generally restricted to the gorges and gullies on the edges of the nominated areas and along waterways	• Non-native vegetation • Habitat connectivity • Vehicle strikes

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Petaurus australis	Yellow-bellied Glider	There is one record in the nominated areas, in GPEC. The closest record outside the nominated areas is < 1 km away from Wilton. There are six records north of GPEC, three records west of Wilton, and one record east of Wilton, all within the Plan Area. The majority of records occur outside the Plan Area to the north-east and south-west	• Habitat connectivity • Vehicle strikes
Petaurus norfolcensis	Squirrel Glider	Records in the nominated areas are limited. There are two records in Wilton and one in GPEC, all of which occur on avoided lands	• Habitat connectivity • Vehicle strikes
Frogs			
Litoria aurea	Green and Golden Bell Frog	Records in the nominated areas are limited. There are 12 records within GPEC and two records within GMAC. Potential habitat has been mapped along Ropes Creek in GPEC in the vicinity of six records made between 1998 and 2012. At the time of public exhibition, it was considered the species could still be present in this area. Targeted surveys of Ropes Creek have since been completed and did not find any individuals to be present (see Supporting Document I)	• Non-native vegetation • Habitat connectivity • Water bodies • Vehicle strikes
Pseudophryne australis	Red-crowned Toadlet	There are no records within the nominated areas. Closest records occur within a few kilometres of the nominated areas. Mapped suitable habitat occurs in scattered patches within the vicinity of gorges and gullies that occur mainly around the edges of the nominated areas	• Rocky areas • Habitat connectivity
Reptiles			
Hoplocephalus bungaroides	Broad-headed Snake	There are no recent records in the nominated areas. There is one historical record from 1970 in the Appin area. Mapped suitable habitat occurs along riparian corridors in gorges and gullies that occur mainly around the edges of the nominated areas	• Karst, caves, crevices, and cliffs • Rocky areas • Vehicle strikes
Varanus rosenbergi	Rosenberg's Monitor	No records occur in the nominated areas and very few records occur in the Cumberland subregion. Records occur at the edges of the subregion near Gordon and Dharawal National Park The species is associated with sandstone areas, particularly to north-east, south-east and north-west of Sydney (OEH, 2017j) and is considered unlikely to occur in the nominated areas, and is not considered further in this Chapter	N/A
Birds			
Anthochaera phrygia	Regent Honeyeater	There are 93 records in the Plan Area which mostly occur in larger patches of woodland in the Londonderry area. Records in the nominated areas are limited, with one occurring in east	• Habitat connectivity

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
		Wilton, one in the middle of GMAC, and five in north-east GPEC	
Artamus cyanopterus cyanopterus	Dusky Woodswallow	There are 97 records in the nominated areas. The species is abundant in and around the Cumberland subregion	• Non-native vegetation • Habitat connectivity
Botaurus poiciloptilus	Australasian Bittern	Records in the nominated areas are limited to one record in the north of GPEC. Six records occur to the north of GPEC and four are scattered between WSA, GMAC and Wilton within the Plan Area	• Habitat connectivity • Water bodies
Calidris ferruginea	Curlew Sandpiper	The species occurs in and around the Cumberland subregion, most frequently closer to the coast. There are 40 records in the Plan Area, the majority of which are concentrated around Windsor. One record occurs in GMAC, within avoided/excluded lands	• Habitat connectivity
Callocephalon fimbriatum	Gang-gang Cockatoo	The species occurs in and around the Cumberland subregion. Records within the nominated areas are limited. One record occurs in the north of GPEC, three in Wilton along the boundary, and 11 in GMAC	• Habitat connectivity
Calyptorhynchus lathami	Glossy Black Cockatoo	The species occurs in and around the Cumberland subregion. Records in the nominated areas are limited. There are two records in the north of GPEC, four in Wilton, and three in GMAC	• Habitat connectivity
Circus assimilis	Spotted Harrier	Records in the nominated areas are limited. One record occurs in GPEC and two in GMAC. The majority of records in the Plan Area occur in the north-east around the Richmond area	• Habitat connectivity
Climacteris picumnus victoriae	Brown Treecreeper	This species occurs sparsely in the Cumberland subregion with the highest density of records occurring in the Blue Mountains and Wolgan Valley regions. Records within the nominated areas are limited. There are three records in the GPEC, four in the east of Wilton, and five throughout GMAC	• Habitat connectivity
Daphoenositta chrysoptera	Varied Sittella	The species occurs in and around the Cumberland subregion. There are 17 records in GPEC, three in WSA, one in Wilton, and 14 in GMAC	• Habitat connectivity
Ephippiorhynchus asiaticus	Black-necked Stork	Records in the nominated areas are limited. There are three records in GPEC and one record in GMAC. Outside the nominated areas within the Plan Area there are a further nine records, the majority of which are located in and around Windsor	• Water bodies
Epthianura albifrons	White-fronted Chat	Records within the nominated areas are limited. There is only one record in the nominated areas, located in GMAC. There are a further three records outside the nominated areas within the Plan Area, located in Liverpool, Windsor, and Scheyville National Park	• Habitat connectivity

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Glossopsitta pusilla	Little Lorikeet	The species is abundant and widespread in and around the Cumberland subregion. There are 17 records in Wilton, five in GPEC, and 23 in GMAC	• Habitat connectivity
Grantiella picta	Painted Honeyeater	The species occurs sparsely in the Cumberland subregion. There are five records within the Plan Area, none of which occur in the nominated areas. Four records occur north of GPEC and one east of WSA in Smithfield	• Non-native vegetation • Habitat connectivity
Haliaeetus leucogaster	White-bellied Sea-eagle	There are several records in the nominated areas (excluding Wilton), including: • One old record and one recent (2019) record in GPEC • Ten records in WSA including several from 2017-2019 • A cluster of relatively recent records (2013) within or just outside the central part of GMAC, and one other record in the southern part of GMAC • Several recent (2018) records just outside the northern part of the GMAC	• Habitat connectivity • Water bodies
Hieraaetus morphnoides	Little Eagle	There are 42 records of the species within the nominated areas or within 5 km of their boundaries. Most records are associated with large patches of open woodland that occur within open grassland areas. Some records are found close to the edges of forests along watercourses. A few records are from woodlands associated with wetlands (Saunders and Debus, 2018a)	• Non-native vegetation • Habitat connectivity
Irediparra gallinacean	Comb-crested Jacana	There are 18 records of the species in the Plan Area, 17 of which occur north of GPEC, with one just north of GMAC. There are no records in the nominated areas	• Habitat connectivity • Water bodies
Ixobrychus flavicollis	Black Bittern	The species occurs sparsely in the Cumberland subregion with the majority of records occurring closer to the coast. There are 16 records in the Plan Area, two of which occur in GPEC	• Habitat connectivity • Water bodies
Lathamus discolor	Swift Parrot	The species is abundant and widespread in and around the Cumberland subregion. There are 266 records in the Plan Area, 26 of which occur in GPEC, eight in GMAC, and one in Wilton	• Habitat connectivity
Limicola falcinellus	Broad-billed Sandpiper	There are no records of the species in the nominated areas or Plan Area. The closest record to the nominated areas is approximately 20 km east towards the coast	• Habitat connectivity
Limosa limosa	Black-tailed Godwit	There are no records in the nominated areas. Eight records occur in the Plan Area, with the closest approximately 2 km west of GPEC	• Habitat connectivity
Lophoictinia isura	Square-tailed Kite	There are 50 records in the Plan Area, with the majority occurring outside the nominated areas north of GPEC. Nine records occur within the	• Non-native vegetation

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
		nominated areas and a further 26 occur within 5 km of the nominated areas (including some outside the Plan Area). The majority of records are from January to April, which represents the post-breeding dispersal phase (Saunders and Debus, 2018b)	• Habitat connectivity
Melithreptus gularis gularis	Black-chinned Honeyeater	The species is widespread in and around the Cumberland subregion, with a higher abundance further north around Glen Davis and the Hunter. There are 48 records in the Plan Area; one in Wilton, two in GPEC and two in GMAC	• Habitat connectivity
Neophema pulchella	Turquoise Parrot	The species occurs in and around the Cumberland subregion with higher densities of records found in Glen Davis, Mellong, and near Yerranderie State Conservation Area. There are 29 records in the Plan Area, six of which occur in GMAC and one in Wilton	• Habitat connectivity
Ninox connivens	Barking Owl	The species occurs in and around the Cumberland subregion. There are 16 records in the Plan Area, one in Wilton and one in GMAC	• Non-native vegetation • Habitat connectivity
Ninox strenua	Powerful Owl	The species occurs in and around the Cumberland subregion. There are 141 records in the Plan Area, including 19 records in GMAC, nine in GPEC and three in Wilton	• Non-native vegetation • Habitat connectivity
Pandion cristatus	Eastern Osprey	There are 4 records in the Plan Area, one of which occurs in GPEC. Relatively more records occur to the east of the Plan Area along the coast	• Habitat connectivity • Water bodies
Rostratula australis	Australian Painted Snipe	The species is sparsely distributed in and around the Cumberland Plain. There are 19 records in the Plan Area, of which one occurs in GPEC and one in GMAC	• Water bodies
Stagonopleura guttata	Diamond Firetail	The species occurs in and around the Cumberland subregion. There are 93 records in the Plan Area of which 15 occur in GPEC, six in GMAC, and one in Wilton	• Habitat connectivity
Stictonetta naevosa	Freckled Duck	The species is sparsely distributed in and around the Cumberland subregion. There are 32 records for the species in the Plan Area, mostly concentrated around Windsor. Of which seven occur in GPEC and one in WSA	• Habitat connectivity • Water bodies
Tyto novaehollandiae	Masked Owl	The species occurs in and around the Cumberland subregion, with higher concentrations occurring around the Central Coast and Nowra. There are 34 records in the Plan Area, of which four occur in GMAC and one in GPEC	• Non-native vegetation • Habitat connectivity
Snail			
Meridolum corneovirens	Cumberland Plain Land Snail	The species is largely endemic to the Cumberland subregion, with a few records occurring just outside. There are 1,097 records in the Plan Area, of which 257 occur in GPEC, 74 in GMAC, 13 in	• Habitat connectivity

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
		WSA and three in Wilton. Records are scattered across the subregion. Most records occur outside the nominated areas or on excluded land	

24.6 ASSESSMENT OF KARST, CAVES, CREVICES, AND CLIFFS

24.6.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with karst, caves, crevices, and cliffs is shown in Table 24-3.

Table 24-3: Species associated with karst, caves, crevices, cliffs, and other geological features

Relevant species	Use and importance of habitat type
Broad-headed Snake	Broad-headed Snake may use rocky areas and crevices for refuge. Adults shelter in rocky outcrops under flat sandstone rocks on exposed cliff edges during autumn, winter, and early spring, then move to adjacent woodland within 500 m of rocky areas during late spring and summer. Pregnant females and juveniles remain in rocky habitat, using cooler, shaded rocks and crevices (DoEE, 2018a)
Large Bent-winged Bat	Large Bent-winged Bat mainly roosts in caves with very specific temperature and humidity regimes. It can also use mines, storm water tunnels, buildings, and other human-made structures. The species disperses widely from breeding colonies (within 300 km). Interrogation of BioNet records suggests no roost sites occur in the nominated areas (OEH, 2021)
Large-eared Pied Bat	Large-eared Pied Bat roosts in sandstone caves, crevices, cliffs, and old mine workings. Habitat within the nominated areas is likely to be used for foraging. Interrogation of BioNet records suggests no roost sites occur in the nominated areas (OEH, 2019g)
Little Bent-winged Bat	Little Bent-winged Bat can roost in the following human-made structures: tunnels, abandoned mines, stormwater drains, culverts, bridges and sometimes buildings during the day. It also roosts in caves and tree hollows. Forages in densely vegetated habitats (OEH, 2019h). Interrogation of BioNet records suggests no roost sites occur in the nominated areas

24.6.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

Locations where karst, caves, crevices, cliffs, and other geological features are most likely to occur in the nominated areas are shown in Map 24-1. These areas are associated with the gorges and gullies around the edges and northern part of Wilton and the southern part of GMAC, including along the Nepean and Cataract rivers. All these areas occur outside the urban capable land and major transport corridors within the nominated areas.

Karst, caves, crevices, cliffs, and other geological features were mapped by:

- Manipulation of a bare earth Digital Elevation Model to produce a layer that showed the mean elevation within a 30 m x 30 m grid surrounding each 1 m elevation grid cell
- Creation of a Topographic Position Index to identify the height of each 1 m cell above/below local mean elevation
- Reclassification of the Topographic Position Index to identify only areas that were high enough above the local mean elevation to create a topographic brake that might support cliffs
- Overlay the cliffs layer with a sandstone geology layer to exclude areas outside sandstone geology

The cliffs layer was validated through inspection of aerial photos and knowledge of the topography and landscape of the nominated areas, as well as site observations during surveys.

24.6.3 NATURE, EXTENT, AND DURATION OF RESIDUAL IMPACTS

AVOIDANCE OF IMPACTS

The steps taken to avoid and minimise impacts of the development in the nominated areas are set out in Chapter 14.

Map 24-1 shows that the areas where karst, caves, crevices, cliffs, and other geological features are most likely to occur have been avoided and do not occur within urban capable land or major transport corridors within the nominated areas.

RESIDUAL IMPACTS

Residual impacts to karst, caves, crevices, and cliffs are unlikely to occur as a result of the urban and industrial development, infrastructure, intensive plant agriculture, or major transport corridors under the Plan within the nominated areas.

24.7 ASSESSMENT OF ROCKY AREAS

24.7.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with rocky areas is shown in Table 24-4.

Table 24-4: Species associated with rocky areas

Relevant species	Use and importance of habitat type
Broad-headed Snake	Broad-headed Snake may use rocky areas for refuge. Adults shelter in rocky outcrops under flat sandstone rocks on exposed cliff edges during autumn, winter, and early spring, then move to adjacent native vegetation (woodland communities) within 500 m of rocky areas during late spring and summer. Pregnant females and juveniles remain in rocky habitat, using cooler, shaded rocks and crevices (DoEE, 2018a)
Red-crowned Toadlet	Red-crowned Toadlet may use rocky areas for breeding and refuge and is largely restricted to the immediate vicinity of these areas. Breeding habitat comprises dense vegetation and debris beside ephemeral creeks and gutters (OEH, 2019j). The species deposits eggs in terrestrial nests beneath rocks and logs or in leaf litter (NSW Scientific Committee, 2002). Outside the breeding period, the species disperses to refuge areas close to breeding sites, which comprise rocks and masses of dense vegetation or thick piles of leaf litter generally on sandstone ridges (OEH, 2019j)

24.7.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

The potential occurrence of rocky areas in each nominated area is described in Table 24-5.

No obvious rock outcrops were observed during targeted surveys done as part of this project (see Chapter 11). However, some areas were not surveyed due to land access restrictions and rock outcrops have the potential to occur.

Table 24-5: Potential occurrence of rocky areas

Nominated area	Potential occurrence of rocky areas
Wilton	Rocky areas may occur on the edges of the nominated area and in the gully lines where the underlying sandstone is exposed
GMAC	Northern part: Several rocky areas comprising small exposures of shale and lithic sandstone may occur
	Southern part: Rocky areas may occur on the edges of the southern section of the nominated area where the underlying sandstone is exposed. Some exposure may also occur along the main gully lines

Nominated area	Potential occurrence of rocky areas
WSA	Several rocky areas comprising small exposures of shale and lithic sandstone may occur
GPEC	Several rocky areas comprising small exposures of shale and lithic sandstone may occur. In the Eastern Creek area there are possible outcrops of basalt and other igneous intrusion

24.7.3 NATURE, EXTENT, AND DURATION OF RESIDUAL IMPACTS

AVOIDANCE OF IMPACTS

The steps taken to avoid and minimise impacts of the development in the nominated areas are set out in Chapter 14.

The relevant species associated with rocky areas, Broad-headed Snake and Red-crowned Toadlet, are generally associated with rocky areas that occur within native vegetation. Approximately 67.2 per cent of native vegetation, including 95.2 per cent of intact condition native vegetation, has been avoided within the nominated areas (not including excluded land) (see Chapter 14). Furthermore, particularly in Wilton and GMAC, rocky areas are more likely to occur on the edges of the nominated areas and in the gully lines where the underlying sandstone is exposed. These areas are generally steep and unsuitable for urban development and have generally been avoided.

RESIDUAL IMPACTS

The nature, extent, and duration of the residual impacts of the urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on rocky areas are set out in Table 24-6.

Table 24-6: Nature, extent, and duration of residual impacts – rocky areas

Species	Nature	Extent	Duration
Broad-headed Snake Red-crowned Toadlet	**Direct impacts:** Rocky areas utilised by these species generally only occur within areas of native vegetation Direct impacts are therefore addressed through impacts to native vegetation and habitat (see Chapter 23) rather than as a prescribed impact	N/A	N/A
	Indirect impacts: The development has the potential to increase bush rock removal in areas of potential habitat for these species as a result of increased human populations in the nominated areas	Risk is highest in publicly accessible habitat areas within and adjacent to the nominated areas	Long-term

24.7.4 GENERAL MITIGATION MEASURES AND IMPLEMENTATION PROCESSES

The collection of bush rock is regulated in NSW and the Plan does not include measures to manage bush rock removal. The removal of bush rock in national parks and nature reserves, as well as state forests and Crown land reserves, is prohibited. Some councils also regulate bush rock removal in council reserves and other bushland areas (DECC, 2009). Furthermore, Councils or other public authorities prepare management plans for many reserves which typically include measures to control public access within reserves, which may reduce the risk of bush rock removal.

24.7.5 ASSESSMENT OF POTENTIAL IMPACTS

An assessment of the potential prescribed impacts from urban and industrial development, infrastructure, intensive plant agriculture and major transport corridors on rocky areas is set out in Table 24-7.

Table 24-7: Assessment of potential prescribed impacts – rocky areas

Relevant species	Assessment of potential prescribed impacts	Residual risk of impacts?
Broad-headed Snake Red-crowned Toadlet	Impacts are unlikely to cause population decline at a local, regional, or state scale because no recent records for the species occur in the nominated areas or nearby, reducing the risk that the species relies to a notable extent on habitat in the vicinity of the nominated areas The removal of bush rock in many reserves is prohibited and management plans for reserves typically include measures to control public access within reserves, which may also reduce the risk of bush rock removal. These existing arrangements are considered adequate for managing the risk of bush rock removal to these species	Unlikely

24.8 ASSESSMENT OF HUMAN-MADE STRUCTURES

24.8.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with human-made structures is shown in Table 24-8.

All relevant species associated with this prescribed impact type are microbat species.

Codes within BioNet records ('observation' and 'microhabitat' codes) were interrogated to identify whether there was data on microbats recorded roosting within the nominated areas (Observation Code 'E'), including under bridges (Microhabitat Code 'BR') or in buildings (Microhabitat Code 'BU').

BioNet records suggest no known roost sites occur for any of the species in the nominated areas except for Southern Myotis within GMAC. The records do not indicate whether these roost sites are associated with human-made structures.

Table 24-8: Species associated with human-made structures

Relevant species	Use and importance of habitat type
Large Bent-winged Bat	The Large Bent-winged Bat mainly roosts in caves with very specific temperature and humidity regimes. The species can also use mines, storm water tunnels, buildings, and other human-made structures. The species disperses widely from breeding colonies (within 300 km) (OEH, 2019e). BioNet records suggest no known roost sites occur in the nominated areas
Eastern False Pipistrelle	Roost requirements for Eastern False Pipistrelle are poorly known. The species is thought to mainly roost in tree hollows, but has also been found under loose bark on trees or in buildings. The species may roost in paddock trees. BioNet records suggest no known roost sites occur in the nominated areas (OEH, 2017c)
Eastern Coastal Free-tailed Bat	Eastern Coastal Free-tailed Bat mainly roosts in tree hollows. It can also roost in human-made structures, including buildings (OEH, 2017d). The species changes breeding sites every few days, making it very difficult to record sites. Occasionally aggregates in large breeding groups (including in buildings). BioNet records suggest no known roost sites occur in the nominated areas
Greater Broad-nosed Bat	Greater Broad-nosed Bat mainly roosts in tree hollows. It can also roost inhuman-made structures, including buildings. Forages along creek and river corridors (OEH, 2017f). BioNet records suggests no known roost sites occur in the nominated areas
Little Bent-winged Bat	Little Bent-winged Bat can roost in the following human-made structures: tunnels, abandoned mines, stormwater drains, culverts, bridges and sometimes buildings during the day. It also roosts in caves and tree hollows. Forages in densely vegetated habitats (OEH, 2019h). BioNet records suggest no known roost sites occur in the nominated areas

Relevant species	Use and importance of habitat type
Southern Myotis	Southern Myotis can roost in the following human-made structures: mine shafts, storm water tunnels, buildings, and under bridges and in culverts. The species also roosts in caves, hollow-bearing trees and dense foliage, and forages over waterbodies within 200 m of roost sites (OEH, 2019l). BioNet records show roost sites have been recorded in GMAC. The records do not indicate whether these roost sites are associated with human-made structures
Yellow-bellied Sheathtail-bat	Yellow-bellied Sheathtail-bat is thought to mainly roost in tree hollows and buildings, and sometimes mammal burrows (OEH, 2017m). BioNet records suggest no known roost sites occur in the nominated areas

24.8.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

It was not possible to map the location of human-made structures at the scale of the nominated areas.

Human-made structures such as mine shafts, storm water channels, old or derelict buildings, bridges and culverts may provide suitable habitat for several species and are likely to occur throughout each of the nominated areas.

24.8.3 NATURE, EXTENT, AND DURATION OF RESIDUAL IMPACTS

AVOIDANCE OF IMPACTS

Human-made structures are likely to occur throughout each of the nominated areas and it was not possible to determine avoidance outcomes for human-made structures. The Plan includes several specific mitigation measures that will avoid and minimise impacts to micro-bat species (see Section 24.8.6).

RESIDUAL IMPACTS

The nature, extent, and duration of the residual impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on human-made structures are set out in Table 24-9.

Table 24-9: Nature, extent, and duration of residual impacts – human-made structures

Species	Nature	Extent	Duration
All relevant micro-bat species	**Direct impacts:** Direct impacts may occur due to removal or upgrade of bridges, culverts, stormwater channels, old buildings and other human-made structures that contain roost sites	Human-made structures within urban capable land and major transport corridors in each nominated area	Long-term
	Indirect impacts: Indirect impacts may occur due to disturbance to individuals using human-made structures though physical disturbance, lighting, or noise due to construction activities, or increased presence of human populations	Human-made structures adjacent to urban capable land and major transport corridors in each nominated area	Temporary or long-term

GREEN AND GOLDEN BELL FROG

Note that an area of 5.6 hectares mapped as suitable Green and Golden Bell Frog habitat occurs within an existing urban area of human-made structures comprising buildings and roads in GPEC (near Ropes Creek) and will be directly impacted by urban and industrial development and infrastructure. The area of habitat was mapped based on:

- The locations of known records
- The riparian corridor joining those records
- A buffer of 1,000 m around the riparian corridor and records that could be used by the species for foraging, shelter, breeding and as migratory habitat for dispersal between water bodies and riparian corridors (Lemckert, 2019)

This area occurs within the buffer and is very unlikely to provide notable habitat or connectivity for the species as it currently comprises buildings and roads. As such, the impacts on this area are not considered further.

24.8.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

This section identifies commitments in the Plan relating to prescribed impacts and general mitigation measures/development controls that are commonly implemented by planning authorities through the development application process and are relevant to managing prescribed impacts. Specific mitigation measures/development controls that will apply to specific species and TECs in certain locations are identified in Section 24.8.6.

This section also summarises the processes to implement the general and specific mitigation measures/development controls for the different development types under the Plan. These processes are described in detail in Chapter 15.

URBAN AND INDUSTRIAL DEVELOPMENT AND INTENSIVE PLANT AGRICULTURE

The Plan includes a commitment (Commitment 5) to mitigate prescribed impacts from urban and industrial development and intensive plant agriculture on TECs, threatened species and their habitat within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Development Control Plans (DCPs) will be prepared for each nominated area that will include development controls to address prescribed impacts. The development controls in DCPs will be implemented through the standard development application process under the EP&A Act that occurs prior to development proceeding.

The Department has prepared a DCP template that provides model provisions to help ensure mitigation measures identified in the Plan to address prescribed impacts are incorporated into DCPs as development controls and are applied consistently across the nominated areas. The DCP template includes both:

- A common set of controls that apply across the nominated areas and inform general biodiversity protection. These controls are commonly implemented by planning authorities to manage prescribed impacts through the development application process – these are identified in Chapter 15 (Table 15-4 to Table 15-13)
- A specific set of controls that apply to specific species and TECs in certain locations. These controls have been identified through this Assessment Report and are needed to address the residual risks that remain after the common set of controls are applied. These are identified in Appendix E of the Plan and Section 24.8.6 below

The common controls included in the DCP template relevant to managing prescribed impacts on micro-bat species due to the disturbance of human-made structures are:

- Where noise or light impacts from development may affect wildlife, measures to manage impacts should be implemented, such as managing the timing of activities and/or installing appropriate noise barriers
- High-intensity outdoor lighting should be designed to avoid light spill into adjoining natural areas
- Development within 100 m of known microbat colonies must include street lighting that does not attract insects

The specific controls included in the DCP template are identified in Section 24.8.6.

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.1.

INFRASTRUCTURE AND MAJOR TRANSPORT CORRIDORS

Commitment 5 includes mitigating prescribed impacts of infrastructure within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Commitment 6 requires mitigating prescribed impacts of the major transport corridors in accordance with the:

- Major transport corridors class of action description, including the NSW State Significant Infrastructure (SSI) (or equivalent) approval for certified major transport corridors
- Specific mitigation measures to address impacts on biodiversity values prescribed in Appendix E of the Plan

Both infrastructure and the major transport corridors will be subject to future environmental assessment and approval processes under the EP&A Act based on detailed design at the time the projects are proposed (see Part 2).

The assessment of the prescribed impacts of infrastructure and the major transport corridors due to the disturbance of human-made structures in Section 24.8.5 led to the identification of several mitigation measures to address impacts on micro-bat species. These mitigation measures are identified in Appendix E of the Plan and Section 24.8.6 below.

To ensure implementation of these mitigation measures for infrastructure, the Department will prepare a guideline under clause 228 of the EP&A Regulation – the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development. The infrastructure guideline must be taken into account when public authorities consider the likely impact of infrastructure on the environment under the EP&A Act through the future environmental assessment process. The mitigation measures identified in Section 24.8.6 to address prescribed impacts on micro-bat species due to the disturbance of human-made structures will be incorporated into the infrastructure guideline.

For the major transport corridors, an action under Commitment 5 requires Transport for NSW to:

> *'Implement specific mitigation measures prescribed in Appendix E and identify and implement additional mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the SSI (or equivalent) approval process, as well as best practice guidelines, including the RMS Biodiversity Guidelines'*

This requirement ensures the mitigation measures identified in Section 24.8.6 to address prescribed impacts on micro-bat species due to the disturbance of human-made structures are implemented through or alongside the future environmental assessment process and based on detailed design of the project.

A detailed description of the processes to implement mitigation measures for infrastructure and the major transport corridors in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 (for infrastructure) and Section 15.6.3 (for the major transport corridors).

24.8.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

An assessment of the potential prescribed impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on species associated with human-made structures is set out in Table 24-10.

Table 24-10: Assessment of potential prescribed impacts – human-made structures

Relevant species	Assessment of potential prescribed impacts	Residual risk of impact
Southern Myotis	Impacts may cause population decline at a local scale because: • Known roost sites occur in the nominated areas (within GMAC) • Many records for the species occur in the nominated areas suggesting the nominated areas are an important area for these species Impacts are unlikely to cause population decline at a regional or State scale because: • Records are widespread across the Cumberland subregion and Sydney Basin bioregion, suggesting the nominated areas are not a stronghold for the species • The species is widely distributed across a coastal band (generally within 100 km of the coast) within NSW both north and south of the Cumberland subregion General mitigation measures are likely to reduce but not completely negate the risk that the development may lead to a population decline at a local scale as there is uncertainty about the location of roosting sites within man-made structures within the nominated areas. The Plan includes a species-specific mitigation measure to address this risk	Yes

Relevant species	Assessment of potential prescribed impacts	Residual risk of impact
Large Bent-winged Bat Eastern Coastal Free-tailed Bat	Impacts may cause population decline at a local scale because: • Many records for the species occur in the nominated areas suggesting the nominated areas are an important area for these species • The bats have been found to roost in derelict mines, stormwater tunnels, buildings, and other man-made structures Impacts are unlikely to cause population decline at a regional or State scale because: • Records are widespread across the Cumberland subregion and Sydney Basin bioregion, suggesting the nominated areas are not a stronghold for the species • The species is widely distributed across a coastal band (generally within 100 km of the coast) within NSW both north and south of the Cumberland subregion BioNet records suggest no known roost sites occur in the nominated areas, therefore, the risk of population decline is low at a local scale. The general mitigation measures will reduce the risk to these species further, but there is uncertainty about the importance of human-made structures for microbat species in the subregion. The Plan includes a species-specific mitigation measure to address this risk	Yes
Little Bent-winged Bat Yellow-bellied Sheathtail-bat	Impacts are unlikely to cause population decline at a local, regional, or State scale because: • BioNet records suggest no known roost sites occur in the nominated areas • Few records occur for the species in the nominated areas compared to other parts of the Cumberland subregion and Sydney Basin bioregion, which suggests the species is less reliant on these areas for persistence in the subregion or region While the risk of population decline is low and the general mitigation measures will reduce the risk to these species further, there is uncertainty about the importance of human-made structures for microbat species in the subregion. The Plan includes a species-specific mitigation measure to address this risk	Yes
Eastern False Pipistrelle Greater Broad-nosed Bat	Impacts are unlikely to cause population decline at a local, regional, or State scale because: • BioNet records suggest no known roost sites occur in the nominated areas • Species appears to mainly roost in tree hollows and impacts on human-made structures are therefore unlikely to substantially affect roosting habitat • Few records occur in the nominated areas compared to other parts of the Cumberland subregion and Sydney Basin bioregion, which suggests these species is less reliant on these areas for persistence in the subregion or region While the risk of population decline is low and the general mitigation measures will reduce the risk to these species further, there is uncertainty about the importance of human-made structures for microbat species in the subregion. The Plan includes a species-specific mitigation measure to address this risk	Unlikely

24.8.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-11 identifies additional specific mitigation measures under Appendix E of the Plan to address residual risks to microbat species due to the development. These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on microbat species.

Table 24-11: Specific mitigation measures – human-made structures

Relevant species	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
All relevant microbat species	Undertake pre-construction surveys prior to removal or disturbance (seasonally dependent, before torpor) to human-made structures to ensure any roosting habitat for microbat species including mine shafts, storm water tunnels, old or derelict buildings, bridges and culverts are retained where possible	Urban and industrial development, infrastructure, and intensive plant agriculture	There is a low risk that pre-construction surveys may not accurately identify roosting sites for various reasons (e.g. because they are undertaken at the wrong time of year)
	Incorporate artificial breeding and roosting habitat (e.g. bat boxes, structural cavities) in the design of bridges associated with the major transport corridors in accordance with relevant guidelines or standards	Major transport corridors	While bat boxes are used widely as a conservation measure for micro-bat species, there is some uncertainty about their effectiveness for some species (Smith, 2002; Rueegger *et al.*, 2020)

The specific measures will be implemented in the same way as the general mitigation measures as described above and in detail in Chapter 15, Sections 15.6.1, 15.6.2 and 15.6.3.

24.9 ASSESSMENT OF NON-NATIVE VEGETATION

24.9.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with the habitat or prescribed impact type is shown in Table 24-12.

Table 24-12: Species/TECs associated with non-native vegetation

Relevant species/TECs	Use and importance of habitat type
Flora	
Acacia bynoeana	These species can occur in areas of non-native vegetation, such as disturbed or partially cleared land, including roadsides or trail margins. However, they mainly rely on native vegetation as habitat All these species were mapped based on expert reports No areas of suitable habitat were mapped outside native vegetation for: • *Acacia bynoeana* • *Grevillea juniperina* • *Persoonia bargoensis* Very small areas of suitable habitat were mapped within areas of non-native vegetation (within areas mapped as 'urban native/exotic'– see Chapter 19) for the following species: • *Pimelea spicata* • *Hibbertia fumana* • *Hibbertia puberula*
Grevillea juniperina subsp. *juniperina*	
Hibbertia fumana	
Hibbertia puberula	
Persoonia bargoensis	
Pimelea spicata	
Bats	
Grey-headed Flying-fox	The species may roost in non-native vegetation with a dense canopy. While blossom from *Eucalyptus* and related genera form a large part of the species diet, non-native trees can form an important part of the diet in urban areas (OEH, 2018f)
Yellow-bellied Sheathtail-bat	
Greater Broad-nosed Bat	

Relevant species/TECs	Use and importance of habitat type
Little Bent-winged Bat	The species primarily use native vegetation or human-made features for roosting. However, some species may occasionally use crevices in non-native trees or dense non-native vegetation for roosting The species prey, such as small insects, may occur within and rely on non-native vegetation to some extent in some areas
Large Bent-winged Bat	
Eastern Coastal Free-tailed Bat	
Eastern False Pipistrelle	
Marsupials	
Spotted-tailed Quoll	The species may use non-native vegetation along waterways for dispersal between areas of suitable habitat. Non-native vegetation may benefit the species by increasing protective vegetation cover along the waterways
Frogs	
Green and Golden Bell Frog	The species may occur in disturbed areas, including non-native vegetation. Habitat comprises water bodies and associated terrestrial habitats with grassy areas and low native or non-native vegetation (DEWHA, 2009c; Lemckert, 2019). The species may use non-native vegetation to disperse between habitat sites Suitable habitat for the Green and Golden Bell Frog that may contain the species has been mapped around St Mary's in GPEC. The area of suitable habitat covers: • The locations of known records • The riparian corridor joining those records • A buffer of 1,000 m around the riparian corridor and records that could be used by the species for foraging, shelter, breeding and as migratory habitat as individuals move between water bodies and riparian corridors (Lemckert, 2019)
Birds	
Dusky Woodswallow	The species occurs primarily in native vegetation (mainly open eucalypt forests and woodland). However, the species may also occur in farmland, usually at the edges of forest or woodland. The species may use deciduous trees for perching
Painted Honeyeater	The species primarily occurs in woodlands and forages on the fruits of mistletoes growing on eucalypts and acacias. The species may forage on planted Silky-Oaks
Little Eagle	The species' prey, such as mammals, may occur within and rely on non-native vegetation to some extent, particularly in the vicinity of urban areas
Square-tailed Kite	
Barking Owl	
Powerful Owl	
Masked Owl	

24.9.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

Non-native vegetation was mapped as part of the native vegetation mapping for the nominated areas and is defined as:

> *Vegetation that is not consistent with floristic composition and landscape positions for native plant community types as defined by the NSW BioNet Vegetation Classification system; most common communities comprise of very few native species or consist of an assorted mix of planted native or exotic trees*

Non-native vegetation occurs within urban capable land in all nominated areas. The location of non-native vegetation within the nominated areas is shown in Map 24-2.

24.9.3 NATURE, EXTENT, AND DURATION OF RESIDUAL IMPACTS

AVOIDANCE OF IMPACTS

The steps taken to avoid and minimise impacts of the development in the nominated areas are set out in Chapter 14.

Avoidance was undertaken in accordance with a set of avoidance criteria (see Box 1, Chapter 14). The criteria included prioritising the avoidance of known habitat for species as indicated by BioNet records or surveys undertaken for the project, including any relevant areas of non-native vegetation where species records occur.

Only very small amounts of non-native vegetation comprising suitable habitat for flora species associated with non-native vegetation will be impacted (see Table 24-13). While large areas of non-native vegetation will be impacted that may affect several bats and bird species, these species are generally more reliant on native vegetation, which was appropriately the focus of avoidance effort. Furthermore, while Grey-headed flying Fox may roost in non-native vegetation and non-native trees can form an important part of the diet for this species in urban areas, avoidance outcomes for this species in relation to non-native vegetation are considered adequate as:

- There are no known Grey-headed Flying Fox camps in the urban capable land
- The species is highly mobile, feeds on fruit and nectar from a variety of vegetation communities, and has access to large areas of intact vegetation surrounding the Plan area
- Substantial areas of native and non-native vegetation will be established in open space areas and along major and residential roads as part of the urban development under the Plan

RESIDUAL IMPACTS

The nature, extent, and duration of the residual impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on non-native vegetation are set out in Table 24-13.

Table 24-13: Nature, extent, and duration of residual impacts – non-native vegetation

Species/TEC	Nature	Extent	Duration

Flora	**Direct impacts:**
	Direct impacts will occur to suitable habitat within non-native vegetation for the following species:
	• *Pimelea spicata*
	• *Hibbertia fumana*
	• *Hibbertia puberula*
	Suitable habitat for the other flora species generally occurs within areas of native vegetation and direct impacts for these species are therefore addressed through impacts to native vegetation and habitat (see Chapter 23)
		Following impacts occur across the nominated areas:
		• *Pimelea spicata*
		  ○ Wilton – 0.6 ha
		  ○ Greater Macarthur – 4.96 ha
		  ○ WSAGA – 2.25 ha
		  ○ GPEC – 0.34 ha
		• *Hibbertia fumana*
		  ○ Wilton – 0.06 ha
		  ○ WSAGA – 1.05 ha
		• *Hibbertia puberula*
		  ○ Wilton – 0.06 ha
		  ○ WSAGA – 1.05 ha
			Long-term

	Indirect impacts: The development may cause a range of indirect impacts to suitable habitat within non-native vegetation for these flora species. Key risks are weed invasion, rubbish dumping, and increased risk of fire	Non-native vegetation adjacent to urban capable lands in each nominated area	Temporary or long-term
Bats	**Direct impacts:** The development may directly impact areas of non-native vegetation that provide foraging habitat for Grey-headed Flying-fox and potential roosting habitat for some microbat species. There are no known Grey-headed Flying-fox camps in the urban capable land	Non-native vegetation within urban capable lands in each nominated area	Temporary or long-term

Species/TEC	Nature	Extent	Duration
	Indirect impacts: There may be a decrease in the abundance of prey for some microbat species due to direct impacts on non-native vegetation potentially impacting prey habitat	Non-native vegetation adjacent to urban capable lands in each nominated area	Temporary or long-term
Marsupials	**Direct impacts:** N/A	N/A	N/A
	Indirect impacts: Removal of non-native vegetation along waterways may reduce vegetation cover that facilitates dispersal of the Spotted-tailed Quoll between areas of suitable habitat	Non-native vegetation within riparian corridors	Temporary or long-term
Green and Golden Bell Frog	**Direct impacts:** The development will directly impact a small amount of non-native vegetation within suitable habitat for this species	0.06 ha in the St Mary's area in GPEC	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to suitable habitat within non-native vegetation for Green and Golden Bell Frog. Key risks are weed invasion, rubbish dumping, and increased risk of fire	Adjacent to urban capable land in the St Mary's area in GPEC	Temporary or long-term
Birds	**Direct impacts:** Direct impacts may occur to non-native vegetation used by Dusky Woodswallow and Painted honeyeater for perching or foraging	Within urban capable land in each nominated area	Long-term
	Indirect impacts: There may be a decrease in the abundance of prey for some bird species due to direct impacts on non-native vegetation potentially impacting prey habitat	Within and adjacent to urban capable land in each nominated area	Temporary or long-term

24.9.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

This section identifies commitments in the Plan relating to prescribed impacts and general mitigation measures/development controls that are commonly implemented by planning authorities through the development application process and are relevant to managing prescribed impacts. Specific mitigation measures/development controls that will apply to specific species and TECs in certain locations are identified in Section 24.9.6.

This section also summarises the processes to implement the general and specific mitigation measures/development controls for the different development types under the Plan. These processes are described in detail in Chapter 15.

URBAN AND INDUSTRIAL DEVELOPMENT AND INTENSIVE PLANT AGRICULTURE

The Plan includes a commitment (Commitment 5) to mitigate prescribed impacts from urban and industrial development and intensive plant agriculture on TECs, threatened species and their habitat within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Development Control Plans (DCPs) will be prepared for each nominated area that will include development controls to address prescribed impacts. The development controls in DCPs will be implemented through the standard development application process under the EP&A Act that occurs prior to development proceeding.

The Department has prepared a DCP template that provides model provisions to help ensure mitigation measures identified in the Plan to address prescribed impacts are incorporated into DCPs as development controls and are applied consistently across the nominated areas. The DCP template includes both:

- A common set of controls that apply across the nominated areas and inform general biodiversity protection. These controls are commonly implemented by planning authorities to manage prescribed impacts through the development application process – these are identified in Chapter 15 (Table 15-4 to Table 15-13)
- A specific set of controls that apply to specific species and TECs in certain locations. These controls have been identified through this Assessment Report and are needed to address the residual risks that remain after the common set of controls are applied. These are identified in Appendix E of the Plan and Section 24.9.6 below

The common controls included in the DCP template relevant to managing prescribed impacts on species associated with non-native vegetation are:

- Manage water cycles and water quality (relevant to Green and Golden Bell Frog)
- Protect riparian corridors (relevant to Spotted-tailed Quoll)
- Control the spread of weeds (relevant to several species above)
- Ensure native trees are planted in open space areas and along major and residential roads as part of the design of new residential areas (relevant to Grey-headed Flying-fox, micro-bat species and birds)

The specific controls included in the DCP template are discussed in Section 24.9.6.

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.1.

INFRASTRUCTURE AND MAJOR TRANSPORT CORRIDORS

Commitment 5 includes mitigating prescribed impacts of infrastructure within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Commitment 6 requires mitigating prescribed impacts of the major transport corridors in accordance with the:

- Major transport corridors class of action description, including the NSW State Significant Infrastructure (SSI) (or equivalent) approval for certified major transport corridors
- Specific mitigation measures to address impacts on biodiversity values prescribed in Appendix E of the Plan

Both infrastructure and the major transport corridors will be subject to future environmental assessment and approval processes under the EP&A Act based on detailed design at the time the projects are proposed (see Part 2).

The assessment of the prescribed impacts of infrastructure and the major transport corridors on species associated with non-native vegetation in Section 24.9.5 led to the identification of several mitigation measures to address impacts on Grey-headed Flying-foxes. These mitigation measures are identified in Appendix E of the Plan and Section 24.9.6 below.

To ensure implementation of these mitigation measures for infrastructure, the Department will prepare a guideline under clause 228 of the EP&A Regulation – the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development. The infrastructure guideline must be taken into account when public authorities consider the likely impact of infrastructure on the environment under the EP&A Act through the future environmental assessment process. The mitigation measures identified in Section 24.9.6 to address prescribed impacts on species associated with non-native vegetation will be incorporated into the infrastructure guideline.

For the major transport corridors, an action under Commitment 5 requires Transport for NSW to:

> *'Implement specific mitigation measures prescribed in Appendix E and identify and implement additional mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the SSI (or equivalent) approval process, as well as best practice guidelines, including the RMS Biodiversity Guidelines'*

This requirement ensures the mitigation measures identified in Section 24.9.6 to address prescribed impacts on species associated with non-native vegetation are implemented through or alongside the future environmental assessment process and based on detailed design of the project.

A detailed description of the processes to implement mitigation measures for infrastructure and the major transport corridors in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 (for infrastructure) and Section 15.6.3 (for the major transport corridors).

24.9.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

An assessment of the potential prescribed impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on species associated with non-native vegetation is set out in Table 24-14.

Table 24-14: Assessment of potential prescribed impacts – non-native vegetation

Relevant species/ TECs	Assessment of potential prescribed impacts	Residual risk of impacts?
Flora	Impacts are unlikely to cause population decline at a local, regional, or State scale because: • These species mainly rely on native vegetation as habitat • Only very small areas of potential habitat within non-native vegetation will be impacted for *Pimelea spicata*, *Hibbertia fumana* and *Hibbertia puberula* relative to areas of unimpacted habitat within native vegetation. The 8.1 ha of impact to *Pimelea spicata* occur as a high number of small areas across all nominated areas	Unlikely
Bats	Impacts are unlikely to cause population decline for micro-bat species at a local, regional, or State scale because: • These species mainly use caves, crevices, human-made structures, or tree hollows within native vegetation for roosting • Substantial areas of native and non-native vegetation will be established in open space areas and along major and residential roads, which is likely to negate any low risk of indirect impacts through reduced prey abundance There is a low risk that impacts may cause population decline for Grey-headed Flying-fox at a local scale due to impacts on foraging habitat. Impacts are unlikely to cause population decline for Grey-headed Flying Fox at a regional or State scale because: • There are no known Grey-headed Flying Fox camps in the urban capable land • The species is highly mobile, feeds on fruit and nectar from a variety of vegetation communities, and has access to large areas of intact vegetation surrounding the Plan area • Substantial areas of native and non-native vegetation will be established in open space areas and along major and residential roads as part of the urban development under the Plan The Plan includes a species-specific mitigation measure to address this risk	Yes for Grey-headed Flying-fox

Marsupials	Impacts are unlikely to cause population decline for Spotted-tail Quoll at a local, regional, or State scale because:
	• Urban capable lands have avoided riparian corridors consistent with the *Water Management Act 2000* along waterways, comprising:
	  ○ Strahler stream order 2 - buffer 20 m either side
	  ○ Strahler stream order 3 - buffer 30 m either side
	  ○ Strahler stream order 4 and above - buffer 40 m either side
	• Development controls will be put in place to protect riparian corridors
		Unlikely

Relevant species/ TECs	Assessment of potential prescribed impacts	Residual risk of impacts?
Green and Golden Bell Frog	Impacts are unlikely to cause population decline for Green and Golden Bell Frog at a local, regional, or State scale because only very small areas of potential habitat within non-native vegetation will be impacted. Furthermore, this impact occurs towards the edge of suitable habitat and distant from the riparian corridor of Ropes Creek and is therefore unlikely to significantly contribute to further fragmentation of areas of suitable habitat. Furthermore, recent targeted surveys along Ropes Creek did not detect the species at this location (see Supporting Document I)	Unlikely
Birds	Impacts are unlikely to cause population decline for these species at a local, regional, or State scale because: • These species mainly rely on native vegetation as habitat • Only small areas of potential habitat within non-native vegetation will be impacted for these species relative to areas of unimpacted habitat within native vegetation • Substantial areas of native and non-native vegetation will be established in open space areas and along major and residential roads	Unlikely

24.9.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-15 identifies additional specific mitigation measures under Appendix E of the Plan to address residual risks to Grey-headed Flying-fox due to the development (these measures will also benefit several other species above, including birds and microbats). These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on this species.

Table 24-15: Specific mitigation measures – non-native vegetation

Relevant species	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
Grey-headed Flying-fox	Establish minimum setbacks for urban development around flying fox camps	Urban and industrial development, infrastructure, and intensive plant agriculture	Setbacks are a well-established mitigation measure for camps
	Retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction		Large trees generally provide the greatest sources of nectar, which is the primary food for the species

The specific measures will be implemented in the same way as the general mitigation measures as described above and in detail in Chapter 15, Sections 15.6.1 and 15.6.2.

24.10 ASSESSMENT OF HABITAT CONNECTIVITY AND MOVEMENT

Habitat connectivity refers to the degree of connectedness of areas of habitat. Habitat connectivity can include:

- Corridors of vegetation linking other areas of habitat
- Isolated patches of habitat that provide 'stepping stones' between other areas of habitat
- Habitat features (such as large trees with hollows) scattered within areas of non-habitat (e.g. urban land) that provide habtiat connectivity between intact areas of habitat

The urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors have the potential to lead to changes and disruption to habitat connectivity. Potential habitat connectivity impacts could occur in all four nominated areas.

BIO MAP

The Biodiversity Investment Opportunities Map (BIO Map) is a key deliverable of the NSW Government's $40 million Green Corridors program. The BIO Map project aimed to achieve better biodiversity outcomes by directing biodiversity investment funding to the strategic locations of greatest benefit.

The BIO Map for the Cumberland subregion covers an area of 275,693 ha, including the Cumberland Plain. Mapping criteria were used to identify and map Priority Investment Areas (PIAs). The PIAs comprise of a network of 87 core areas and 27 regional biodiversity corridors within the Cumberland subregion. The 87 core areas include all of the priority conservation lands identified by the Cumberland Plain Recovery Plan (DECCW, 2011).

The total area represented within the mapped PIAs is 42,124 ha. This represents approximately 15 per cent of the Cumberland subregion or approximately 61 per cent of all mapped vegetation within the subregion.

BIO Map identifies PIAs where the protection and management of native vegetation is likely to maximise benefits to biodiversity within the Cumberland subregion. The PIAs comprise:

- BIO Map core areas: large areas of native vegetation and habitat where management will be of greatest benefit to the conservation of biodiversity values. These areas represent the habitat in the subregion most likely to support species persistence and interactions between species and landscape scale ecological processes
- BIO Map regional corridors: linear areas that link core areas and play a crucial role in maintaining connections between species populations that would otherwise be isolated and at greater risk of local extinction

24.10.1 LIST OF RELEVANT SPECIES AND TECS

Habitat connectivity is relevant to all species to some extent for:

- Movement across home ranges/dispersal between areas of suitable habitat
- Breeding or reproduction
- Foraging
- Other important life cycle events

Species reliant on habitat connectivity have been categorised into five groups:

- Fauna more likely to need large habitat corridors and/or large areas of intact native vegetation
- Fauna able to utilise narrower habitat corridors or riparian corridors or waterways
- Fauna able to utilise scattered and/or degraded patches of native vegetation within an urban or agricultural matrix
- Fauna that are relatively immobile and move only short distances
- TECs that rely on habitat connectivity for effective airborne pollination and the movement of pollinators

Table 24-16 shows the groupings for species predicted to occur in the nominated areas.

Table 24-16: Species/TECs associated with areas of habitat connectivity

Group	Relevant species/TECs	Use and importance of habitat type
Large habitat corridors and/or large areas of intact native vegetation	• Koala Most gliders and owls and some birds: • Large-eared Pied Bat • Squirrel Glider • Yellow-bellied Glider • Masked Owl • Barking Owl • Powerful Owl • Gang-gang Cockatoo • Glossy Black Cockatoo	May use large habitat corridors for dispersal between larger patches of suitable habitat, including breeding areas, as well as for foraging

Group	Relevant species/TECs	Use and importance of habitat type
	• Regent Honeyeater • Black-chinned Honeyeater • Brown Treecreeper	
	Raptors: • White-bellied Sea-Eagle • Little Eagle • Square-tailed Kite	
Smaller habitat corridors or riparian corridors or waterways	Smaller marsupials: • Eastern Pygmy-possum • Spotted-tailed Quoll	May use smaller habitat corridors for dispersal between larger patches of suitable habitat, including breeding areas, as well as for foraging Spotted-tailed Quoll relies on habitat connectivity to breed as quolls are solitary and come together to breed
	Birds associated with riparian corridors and/or waterways, including: • Australasian Bittern • Freckled Duck • Comb-crested Jacana • Black Bittern • White-fronted Chat • Eastern Osprey • Curlew Sandpiper • Broad-billed Sandpiper • Black-tailed Godwit	Water birds use waterways and riparian corridors and associated vegetation for shelter, foraging, as well as dispersal between other areas of suitable habitat
Scattered and/or degraded native vegetation within a matrix	• Grey-headed Flying-fox Microbats: • Southern Myotis • Little Bent-winged Bat • Large Bent-winged Bat • Eastern Freetail-bat • Eastern False Pipistrelle • Yellow-bellied Sheathtail-bat	Microbats and birds may use scattered native vegetation for roosting or resting, to move within areas of foraging habitat, or to access other larger areas of suitable habitat for foraging
	Birds: • Dusky Woodswallow • Spotted Harrier • Little Lorikeet • Diamond Firetail • Swift Parrot • Turquoise Parrot • Varied Sittella • Painted Honeyeater	
	• Green and Golden Bell Frog	While the species appears to generally be associated with a single water body for general activities, it is highly mobile and can move some distance as part of migrations to and from breeding sites (Lemckert,

Group	Relevant species/TECs	Use and importance of habitat type
		2019). Movements of up to 5 km may be common and the species may disperse up to 10 km (DoEE, 2018a)
Relatively immobile and moves only short distances	• Cumberland Plain Land Snail • Red-crowned Toadlet	Little is known about Cumberland Plain Land Snail dispersal patterns or over what distances individuals can move (OEH, 2019c). Most populations are small and isolated. The NSW SoS program identifies several actions to ensure connectivity between population, including implementing 'open structure design' when designing structures such as roads which may isolate patches of habitat (EES, 2020) Red-crowned Toadlets are a localised species that are largely restricted to the immediate vicinity of suitable breeding habitat. The species is usually found as small discrete scattered populations along sandstone ridges
TECs	• All TECs	TECs rely on habitat connectivity for effective airborne pollination and the movement of pollinators

24.10.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

Key areas of habitat connectivity in the nominated areas are shown in Map 24-3 and described in Table 24-17.

Habitat connectivity was mapped by:

- Identifying BIO Map regional corridors and core areas. These corridors/core areas are likely to be the most important areas of habitat connectivity in the nominated areas for most species. EES had only identified BIO Map corridors within the boundaries of the Cumberland subregion. To undertake the mapping for the small parts of the nominated areas outside the Cumberland subregion the Priority Conservation Lands layer (DECCW, 2010) (EES used this layer as basis for BIO Map) or the native vegetation map (see Chapter 19) was used to extend the BIO Map corridor mapping
- Identifying local corridors using the native vegetation mapping to identify connected patches of native vegetation. This was done visually in GIS, with only contiguous patches identified as being connected
- Identify any remaining native vegetation not within a regional corridor or local corridor as:
    - Connected – within 100 m of another patch of woody vegetation
    - Isolated – greater than 100 m from another patch of woody vegetation

The categories of habitat connectivity identified in Map 24-3 are:

- BIO Map corridors, categorised as either
    - BIO Map Regional Corridor / BIO Map Regional Corridor and Core Area
    - BIO Map Regional Corridor - extended to match PCLs
    - BIO Map Regional Corridor - extended to match vegetation
- Local corridor
- Connected vegetation
- Isolated vegetation

Table 24-17: Key areas of habitat connectivity in the nominated areas

Nominated area	BIO Map regional corridors/core areas	Local corridors	Connected and isolated vegetation
Wilton	Occur around the edges of the entire nominated area and across the middle of the northern part of the nominated area associated with the Nepean River and the middle of the southern part of the nominated area	One large corridor occurs on the eastern side of the nominated area between the Hume Motorway and Wilton Road connected to the BIO Map regional corridors/core areas to the east of the nominated area. The corridor is a 'dead end' and does not connect to other native vegetation to the south or west of the nominated area Primary and tertiary Koala corridors occur in Wilton	Connected vegetation occurs in scattered areas mainly towards the edges of the nominated area adjacent to BIO Map regional corridors/core areas Isolated vegetation occurs in only a few very small patches in the middle parts of the nominated area
GMAC	Occur around the edges of the entire southern part of the nominated area and across the middle of the southern part in three locations associated with waterways. The corridors/core areas connect native vegetation associated with the Cataract River to the west of the nominated area with large areas of native vegetation to the east of the nominated area	One corridor occurs across the middle of the southern part of the nominated area associated with a waterway. The corridor connects regional corridors/core areas to the east and north within the nominated area with native vegetation to the west of the nominated area Primary, secondary and tertiary Koala corridors occur in GMAC. There are several east-west corridors which provide crucial linkages between the Nepean River and Georges River habitat corridors	Connected vegetation occurs in scattered areas across the nominated area mainly in the southern part Isolated vegetation occurs in only a few very small patches in the middle parts of the nominated area
WSA	Occur in the eastern part of the nominated area associated with Wianamatta (South Creek) and Kemps Creek. A regional corridor/core area connects Wianamatta (South Creek) and Kemps Creek in the south-eastern corner of the nominated area in the Kemps Creek area	Two corridors occur in the middle part of the nominated area associated with Badgerys Creek and Cosgrove Creek. The Cosgrove Creek corridor is a 'dead end' and does not connect to other native vegetation. The Badgerys Creek corridor continues outside the nominated area as a narrow strip of native vegetation	Connected vegetation occurs in scattered areas mainly in the middle and north-eastern part of the nominated area Isolated vegetation occurs in only a few very small patches in the middle parts of the nominated area
GPEC	Occur in the northern part of the nominated area around Wianamatta Regional Park and the southern part around Orchard Hills. Two corridors connect Wianamatta Regional Park and Orchard Hills associated with Wianamatta (South Creek) and	No corridors occur within the nominated area	Connected vegetation occurs in scattered areas across the nominated area Isolated vegetation occurs in a few very small patches across the nominated area

	Ropes Creek. A third corridor connects native vegetation at Orchard Hills to native vegetation to the west of the nominated area near Mulgoa Road along a drainage line		

24.10.3 NATURE, EXTENT, AND DURATION OF RESIDUAL IMPACTS

AVOIDANCE OF IMPACTS

The steps taken to avoid and minimise impacts of the development in the nominated areas are set out in Chapter 14.

Avoidance of impacts in each of the nominated areas is discussed below.

Wilton

The vast majority of BIO Map regional corridors/core areas have been avoided in Wilton. Koala was specifically identified in the avoidance criteria as a priority throughout the project. Following public exhibition, more land was avoided along the Nepean River in Wilton to protect the integrity and functionality of the Koala corridor along the river, and to ensure that the corridor is an average of 390-425 m wide (as recommended by the Office of the NSW Chief Scientist & Engineer).

GMAC

The vast majority of BIO Map regional corridors/core areas have been avoided in GMAC. Koala was specifically identified in the avoidance criteria as a priority throughout the project. Following public exhibition, more land was avoided along the Nepean River and Menangle Creek in GMAC to protect the integrity and functionality of the Koala corridors in these areas, and to ensure that the corridors are an average of 390-425 m wide (as recommended by the Office of the NSW Chief Scientist & Engineer).

WSA

The vast majority of BIO Map regional corridors/core areas have been avoided in WSA.

GPEC

The vast majority of BIO Map regional corridors/core areas have been avoided in GPEC.

RESIDUAL IMPACTS

The nature, extent, and duration of the residual impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on habitat connectivity are set out in Table 24-18.

Table 24-18: Nature, extent, and duration of residual impacts – habitat connectivity

Nominated area	Nature	Extent	Duration
Wilton	**Direct impacts:** The main direct impact occurs in the southern part of the nominated area where the development will remove part of a corridor/core area that connects native vegetation either side of the nominated area in this location. The impact reduces the width of the corridor/core area by about half. Connectivity is maintained to the south and east of the impacted area. In all other areas, direct impacts occur only to the edges of corridors/core areas in a few locations and connectivity along these areas is maintained There are very minor direct impacts to the local corridor on the eastern side of the nominated area between the Hume Motorway and Wilton Road The majority of impacts to connected vegetation occur to smaller scattered patches in the middle of the nominated area and to the edge of larger areas of connected vegetation where it occurs adjacent to BIO Map regional corridors/core areas around the nominated area	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 70 ha (6.7%) • Local corridor – 6.5 ha (3.3%) • Connected vegetation – 125.9 ha (23.2%) • Isolated vegetation – 1 ha (45.5%)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands/transport corridors	Temporary or long-term
GMAC	**Direct impacts:** Direct impacts occur only to the edges of corridors/core areas in a few locations. There are no locations where direct impacts completely sever or significantly narrow a core area/corridor and connectivity is maintained for these areas of habitat connectivity across all parts of the nominated area The vast majority of the local corridor in the middle of the southern part of the nominated area has been avoided and is not directly impacted. Impacts occur only to the edges of the corridor and connectivity is maintained in this location across the nominated area The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in the southern part of the nominated area. In these cases, the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 60.7 ha (2.9%) • Local corridor – 20.2 ha (12.8%) • Connected vegetation – 189.6 ha (18.9%) • Isolated vegetation – 1.4 ha (11.8%)	Long-term
	Indirect impacts:	**Indirect impacts:**	Temporary or long-term

Nominated area	Nature	Extent	Duration
	The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance Further, connectivity will be disrupted for two east-west corridors which link the Nepean and Georges River through GMAC through installation of Koala exclusion fencing. The purpose of this is to exclude Koalas from corridors which are too narrow and may pose dangers to the species. As habitat within these corridors will be avoided by development and protected for other biodiversity and amenity values, fencing of these corridors is considered an indirect impact as opposed to a direct impact	Areas of habitat connectivity adjacent to urban capable lands/transport corridors, in addition to two east-west corridors through GMAC which provide linkages between the Georges River and Nepean River	
WSA	**Direct impacts:** The vast majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impact occurs in the south-eastern part of the nominated area where the development will remove the majority of a corridor/core area that connects Wianamatta (South Creek) and Kemps Creek in the Kemps Creek area. While this area is identified as a regional corridor, connectively has already been completely severed in this location by existing industrial land use. In all other areas, direct impacts occur only to the edges of corridors/core areas in a few locations and connectivity along these areas is maintained The majority of local corridors have been avoided and will not be directly impacted. Direct impacts occur: • At Cosgrove Creek in the middle part of the nominated area where the OSO severs the riparian corridor in two locations • At Badgerys Creek in the middle part of the nominated area where the OSO severs the riparian corridor in one location The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in the north-eastern, middle, and southern parts of the nominated area. In some cases, the impacts will sever or reduce connectivity between this connected vegetation and other areas of connected vegetation within and outside the nominated area	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 52.4 ha (16.5%) • Local corridor – 39.2 ha (31.6%) • Connected vegetation – 309.8 ha (55.9%) • Isolated vegetation – 10.2 ha (63.7%)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands/transport corridors	Temporary or long-term

Nominated area	Nature	Extent	Duration
GPEC	**Direct impacts:** The majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impacts occur: • Within Wianamatta Regional Park where the OSO severs the eastern part of the regional park that is connected to Ropes Creek with the western part of the park • Along Wianamatta (South Creek) where the OSO directly impacts the Wianamatta (South Creek) riparian corridor and severs the narrow connection along the corridor that links Wianamatta Regional Park and Orchard Hills In all other areas direct impacts have been avoided, except in the western part of the nominated area near Glenmore Park where there is a small direct impact to the edge of a corridor/core area No local corridors occur within the nominated area The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in some parts of the nominated area. In these cases, the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas	**Direct impacts:** The following categories of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 189.7 ha (5.8%) • Local corridor – 0 ha (0%) • Connected vegetation – 194 ha (17.5%) • Isolated vegetation – 0.5 ha (5.9%)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands/transport corridors	Temporary or long-term

24.10.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

This section identifies commitments in the Plan relating to prescribed impacts and general mitigation measures/development controls that are commonly implemented by planning authorities through the development application process and are relevant to managing prescribed impacts. Specific mitigation measures/development controls that will apply to specific species and TECs in certain locations are identified in Section 24.10.6.

This section also summarises the processes to implement the general and specific mitigation measures/development controls for the different development types under the Plan. These processes are described in detail in Chapter 15.

URBAN AND INDUSTRIAL DEVELOPMENT AND INTENSIVE PLANT AGRICULTURE

The Plan includes a commitment (Commitment 5) to mitigate prescribed impacts from urban and industrial development and intensive plant agriculture on TECs, threatened species and their habitat within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Development Control Plans (DCPs) will be prepared for each nominated area that will include development controls to address prescribed impacts. The development controls in DCPs will be implemented through the standard development application process under the EP&A Act that occurs prior to development proceeding.

The Department has prepared a DCP template that provides model provisions to help ensure mitigation measures identified in the Plan to address prescribed impacts are incorporated into DCPs as development controls and are applied consistently across the nominated areas. The DCP template includes both:

- A common set of controls that apply across the nominated areas and inform general biodiversity protection. These controls are commonly implemented by planning authorities to manage prescribed impacts through the development application process – these are identified in Chapter 15 (Table 15-4 to Table 15-13)
- A specific set of controls that apply to specific species and TECs in certain locations. These controls have been identified through this Assessment Report and are needed to address the residual risks that remain after the common set of controls are applied. These are identified in Appendix E of the Plan and Section 24.10.6 below

The common controls included in the DCP template relevant to managing prescribed impacts associated with habitat connectivity are:

- Maintain waterways of Strahler order 2 or higher in a natural state, including riparian corridors
- Design road crossings of waterways to minimise impacts to vegetated riparian corridors and species movements
- Retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible
- Retain areas of high density proteaceae shrubs where possible, particularly along riparian corridors
- Plant native trees in open space areas and along major and residential roads as part of the design of new residential areas (particularly relevant to Grey-headed Flying-fox, micro-bat species and birds)
- A range of controls that would mitigate indirect impacts on habitat that forms part of habitat corridors, including water cycle management and water quality and the spread of weeds

The specific controls included in the DCP template are discussed in Section 24.10.6.

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

It is also important to note that the conservation program under the Plan (see Part 2) will result in:

- Protecting a minimum of 5,325 hectares of native vegetation and habitat in the subregion (Commitment 8)
- Undertake ecological restoration of up to 25 per cent of the offset target for native vegetation (Commitment 13)
- Managing landscape threats in strategic locations to improve habitat values, including weeds (Commitment 15) and pests (Commitment 16) and fire (Commitment 17)

Importantly, the strategic conservation areas (SCAs) where these commitments will be delivered represent the areas in the Cumberland subregion that are considered most likely to be viable in the long-term and to maximise ecological function and connectivity across the landscape. In determining the location of the SCAs, priority was given to including the largest, best condition and best-connected areas of native vegetation remaining in the subregion (see Part 2).

INFRASTRUCTURE AND MAJOR TRANSPORT CORRIDORS

Commitment 5 includes mitigating prescribed impacts of infrastructure within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Commitment 6 requires mitigating prescribed impacts of the major transport corridors in accordance with the:

- Major transport corridors class of action description, including the NSW State Significant Infrastructure (SSI) (or equivalent) approval for certified major transport corridors
- Specific mitigation measures to address impacts on biodiversity values prescribed in Appendix E of the Plan

Both infrastructure and the major transport corridors will be subject to future environmental assessment and approval processes under the EP&A Act based on detailed design at the time the projects are proposed (see Part 2).

The assessment of the prescribed impacts of infrastructure and the major transport corridors associated with habitat connectivity in Section 24.10.5 led to the identification of several mitigation measures. These mitigation measures are identified in Appendix E of the Plan and Section 24.10.6 below.

To ensure implementation of these mitigation measures for infrastructure, the Department will prepare a guideline under clause 228 of the EP&A Regulation – the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development. The infrastructure guideline must be taken into account when public authorities consider the likely impact of infrastructure on the environment under the EP&A Act through the future environmental assessment process. The mitigation measures identified in Section 24.10.6 to address prescribed impacts associated with habitat connectivity will be incorporated into the infrastructure guideline.

For the major transport corridors, an action under Commitment 5 requires Transport for NSW to:

> *'Implement specific mitigation measures prescribed in Appendix E and identify and implement additional mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the SSI (or equivalent) approval process, as well as best practice guidelines, including the RMS Biodiversity Guidelines'*

This requirement ensures the mitigation measures identified in Section 24.10.6 to address prescribed impacts associated with habitat connectivity are implemented through or alongside the future environmental assessment process and based on detailed design of the project.

A detailed description of the processes to implement mitigation measures for infrastructure and the major transport corridors in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 (for infrastructure) and Section 15.6.3 (for the major transport corridors).

24.10.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

The nominated areas are highly fragmented and key areas of connectivity generally occur along riparian corridors, within steeper land and gully areas, particularly around the edges of Wilton and southern GMAC.

The development will generally reduce habitat connectivity across the nominated areas for species and TECs mainly due to the removal of many smaller connected patches of habitat, which will often generally leave the remaining larger patches along riparian corridors and within steeper land and gully areas more isolated to some extent. This will have a greater impact on the group of species associated with scattered and/or degraded native vegetation within a matrix.

While a reduction in habitat connectivity will occur, the nominated areas are highly fragmented and the majority of key areas of habitat connectivity will be maintained, including the majority of BIO Map core areas and corridors.

An assessment of the potential prescribed impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on species associated with habitat connectivity is set out in Table 24-19.

Table 24-19: Assessment of potential prescribed impacts – habitat connectivity

Relevant species	Assessment of potential prescribed impacts	Residual risk of impacts?
Species associated with large habitat corridors and/or large areas of intact native vegetation	Impacts are unlikely to cause population decline at a local, regional, or State scale for species associated with large habitat corridors and/or large areas of intact native vegetation (BIO Map corridors/core areas) because: • The vast majority of these areas have been avoided and will not be impacted • Direct impacts generally occur only to the edges of corridors/core areas. There are few locations where direct impacts completely sever or significantly narrow a core area/corridor and connectivity is maintained for these areas The most notable impacts occur: • Within Wianamatta Regional Park • Along Wianamatta (South Creek) where the OSO directly impacts Wianamatta (South Creek) riparian corridor • Within GMAC where two east-west habitat corridors will be fenced to prevent fauna such as Koala from entering the corridors (as part of mitigation measures to protect Koala from landscape threats) The commitments and general mitigation measures are generally considered adequate to manage any residual risks of impacts to habitat connectivity for this group of species. Potential residual risks remain for Koala and impacts associated with the OSO. The Plan includes specific measures to address these risks	Potentially for Koala and impacts associated with OSO
Species associated with smaller habitat corridors or riparian corridors or waterways	Impacts are unlikely to cause population decline at a local, regional, or State scale for species associated with smaller habitat corridors or riparian corridors (local corridors) because: • The vast majority of these areas have been avoided and will not be impacted • Impacts often occur only to the edges of the local corridors and connectivity is maintained for these areas The most notable impacts occur in WSA: • At Cosgrove Creek in the middle part of the nominated area where the OSO severs the riparian corridor in two locations • At Badgerys Creek in the middle part of the nominated area where the OSO severs the riparian corridor in one location The commitments and general mitigation measures are generally considered adequate to manage any residual risks of impacts to habitat connectivity for this group of species. Potential residual risks remain for impacts associated with the OSO. The Plan includes a specific measure to address these risks	Potentially for impacts associated with OSO
Species associated with scattered and/or degraded native vegetation within a matrix	Impacts are unlikely to cause population decline at a local, regional, or State scale for species associated with scattered and/or degraded native vegetation (connected vegetation) because impacts generally occur to: • Smaller scattered patches, where patches will be completely cleared • To the edges of larger patches where the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation The most notable impacts occur in WSA, where in some cases, impacts will sever or reduce connectivity between connected vegetation and other areas of vegetation within and outside the nominated area. These impacts may reduce connectivity in this part of the nominated area for microbats and smaller birds The commitments and general mitigation measures are generally considered adequate to manage any residual risks of impacts to habitat connectivity for this group of species	Unlikely

Relevant species	Assessment of potential prescribed impacts	Residual risk of impacts?
Species that are relatively immobile and move only short distances	Red-crowned Toadlet: impacts are unlikely to cause population decline at a local, regional, or State scale for this species as there are no records within the nominated areas, and mapped suitable habitat occurs in scattered patches within the vicinity of gorges and gullies that occur mainly around the edges of the urban capable land, where habitat connectivity will be maintained Cumberland Plain Land Snail: impacts may potentially cause population decline at a local, regional, and State scale for this species. Little is known about this species dispersal patterns or over what distances individuals can move (OEH, 2019c). Most populations are small and isolated. Records for the species are scattered across the Cumberland subregion. However, where records occur within the nominated areas, most occur on excluded land and many occur on land avoided for biodiversity, including around the edges of GPEC and along riparian corridors in WSA and GPEC. The development is likely to reduce habitat connectivity for this species, associated particularly with the removal of many smaller connected and more isolated patches of Cumberland Plain Woodland, leaving populations in remaining larger patches more isolated to some extent The commitments and general mitigation measures are generally considered adequate to manage any residual risks of impacts to habitat connectivity for this group of species. Potential residual risks remain for Cumberland Plain Land Snail. The Plan includes a specific measure to address these risks	Potentially for the land snail
TECs/flora species	The development will reduce habitat connectivity across the nominated areas for TECs and flora habitat due to the removal of many smaller connected and more isolated patches of TECs, causing the isolation of more intact, larger patches of TECs. This is due to vegetation removal and associated reduced movement of mobile pollinators such as birds and bats TECs (and associated flora species) within the Plan Area, at a local, regional and State scale, are already highly fragmented with the majority of key areas of habitat connectivity being maintained, including the majority of BIO Map core areas and corridors and riparian corridors The commitments and general mitigation measures are generally considered adequate to manage any residual risks of impacts to habitat connectivity for this group of TECs and species	Unlikely

24.10.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-20 identifies additional specific mitigation measures under the Plan to address residual risks due to the development. These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on these species.

Table 24-20: Specific mitigation measures – habitat connectivity

Relevant species/TECs	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
• Koala	The Plan includes the following Koala-specific commitments: • Commitment 7 to protect Koala corridors from prescribed impacts, such as through installing exclusion fencing to separate Koalas from development threats, and installing connectivity	Urban and industrial development, infrastructure, and major transport corridors	There are inherent uncertainties with regards to measures to protect Koala habitat connectivity (such as success of exclusion fences in keeping dogs out of Koala corridors). However, protection of Koalas is a key focus of the Plan, and

Relevant species/TECs	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
	structures to support corridor functionality • Commitment 10 to establish the Georges River Koala Reserve and undertake habitat restoration to support north-south connectivity • Commitment 12 to protect Koala corridors in the region • Commitment 13, Action 4 to undertake restoration to widen Koala corridors • A range of Koala-specific measures in Appendix E of the Plan to protect Koala corridors from habitat degradation and threats due to development		ongoing monitoring and review of both the Plan's implementation and the local Koala population means that any future potential issues will be identified and addressed as part of the Plan's evaluation program. As a result, the risk of failure is considered low
• Eastern Pygmy-possum • Spotted-tailed Quoll • Birds associated with riparian corridors	The Plan includes a commitment to ensure major transport corridors, including the OSO are designed to avoid and minimise impacts to areas of potential habitat connectivity, particularly vegetation in riparian corridors (Commitment 3)	Major transport corridors	Outcome not possible to determine at this stage
• Cumberland Plain Land Snail	The Plan includes a specific mitigation measure to implement 'open structure design' when designing structures such as roads which may isolate patches of habitat, consistent with the critical actions for this species under the Save our Species program (EES, 2020)	Urban and industrial development and intensive plant agriculture	Outcome not possible to determine at this stage. Mitigation measures is consistent with critical actions for this species under the Save our Species program (EES, 2020)

The specific measures will be implemented in the same way as the general mitigation measures as described above and in detail in Chapter 15, Sections 15.6.1, 15.6.2 and 15.6.3.

24.11 ASSESSMENT OF WATER BODIES AND HYDROLOGICAL PROCESSES

24.11.1 LIST OF RELEVANT SPECIES AND TECS

WATER BODIES

The list of species or TECs associated with water bodies is shown in Table 24-21.

Table 24-21: Species/TECs associated with water bodies

Relevant species/TECs	Use and importance of habitat type
Green and Golden Bell Frog	The species uses water bodies for breeding and foraging. While it appears to generally be associated with a single water body for general activities, records

Relevant species/TECs	Use and importance of habitat type
	suggest the species is highly mobile and can move some distance as part of migrations to and from breeding sites (Lemckert, 2019). Movements of up to 5 km may be common and the frog may disperse up to 10 km (DoEE, 2018a). Breeding occurs after heavy rains or storms and spawn is laid among aquatic vegetation (DEWHA, 2009b)
Southern Myotis	The species uses water bodies for foraging. It forages over streams and pools, including dams, on insects and small fish (OEH, 2019l)
White-bellied Sea-eagle	Occurs near large areas of open water including larger rivers, swamps, lakes, and the ocean, or in the vicinity of freshwater swamps, lakes, reservoirs, billabongs, and saltmarsh. Uses waterbodies for foraging. Feeds mainly on fish and freshwater turtles, but also waterbirds, reptiles, and mammals. Breeding habitat is constrained to living or dead mature trees within forests or tall woodland within 1 km of rivers, lakes, large dams or creeks, wetlands and coastlines (OEH, 2017l)
Australasian Bittern	The species uses waterbodies for shelter, foraging and breeding. Inhabits permanent freshwater wetlands with tall, dense vegetation. Shelters during the day amongst dense reeds or rushes and feeds on frogs, fish, yabbies, and insects (OEH, 2018b)
Black-necked Stork	The species uses water bodies for foraging and builds large nests high in tall trees close to water. Primary habitat is floodplain wetlands (swamps, billabongs, watercourses, and dams) of major coastal rivers. Secondary habitat includes minor floodplains, coastal sandplain wetlands and estuaries. It usually forages in water 5-30 cm deep for vertebrate and invertebrate prey (OEH, 2017b)
Comb-crested Jacana	The species inhabits permanent freshwater wetlands with a good cover of floating vegetation or fringing vegetation and uses water bodies for breeding and foraging. It feeds primarily on insects and other invertebrates (OEH, 2018d)
Black Bittern	The species inhabits terrestrial and estuarine wetlands, generally in areas of permanent water and dense vegetation and uses water bodies for breeding and foraging. It feeds on frogs, reptiles, fish, and invertebrates. Nests are built on a branch overhanging water (OEH, 2018c)
Eastern Osprey	Inhabits coastal areas, especially the mouths of large rivers, lagoons and lakes and uses water bodies for foraging. Feeds on fish over open water. Nests are made in dead trees or branches, usually within one kilometre of the sea (OEH, 2018e)
Australian Painted Snipe	Inhabits swamps, dams and nearby marshy areas and uses water bodies or fringing habitat for foraging and breeding. Forages on mud flats and in shallow water. Feeds on worms, molluscs, insects, and some vegetation. Nests on the ground in tall vegetation, such as grasses, tussocks or reeds (OEH, 2017a)
Freckled Duck	Inhabits freshwater swamps and creeks with heavy growth of Cumbungi, Lignum or Tea-tree. During drier times, the species inhabits more permanent waters such as lakes, reservoirs, farm dams and sewage ponds. Rests in dense cover, usually in deep water. Nests occur in dense vegetation at or near water level (OEH, 2017e)

HYDROLOGICAL PROCESSES

The list of species or TECs associated with hydrological processes is shown in Table 24-22 and TECs have been grouped based on the potential risk of impacts from changes to hydrological processes associated with the development.

Table 24-22: Species/TECs associated with hydrological processes

Relevant species/TECs	Use and importance of habitat type
Higher Risk TECs	
Castlereagh Scribbly Gum Woodland in the Sydney Basin Bioregion	Higher risk TECs are those that either:

Relevant species/TECs	Use and importance of habitat type
Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion	• Directly reliant on hydrological processes for the maintenance of their floristic assemblage, or • Are located in landscape positions where processes such as regular flooding and deposition are key to maintaining the edaphic conditions that support the floristic assemblage, or • Are particularly susceptible to erosion, or are considered particularly susceptible to changes in water quality and nutrient load
Freshwater Wetlands on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions	
River-flat Eucalypt Forest on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions.	
Shale Gravel Transition Forest in the Sydney Basin Bioregion	
Shale Sandstone Transition Forest in the Sydney Basin Bioregion	
Swamp Oak Floodplain Forest of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions	
Lower Risk TECs	
Cumberland Plain Woodland in the Sydney Basin Bioregion	Lower risk TECs are those that occur in landscape positions where hydrological processes have a lower level of influence on species assemblage or edaphic conditions
Moist Shale Woodland in the Sydney Basin Bioregion	
Higher Risk threatened flora species	
Allocasuarina glareicola	Higher risk threatened flora species are those that either: • Grow in waterbodies or swampy areas, or • Require regular inundation and deposition to maintain edaphic conditions, or • Are strongly associated with a higher risk TEC, or • Are higher specialised with regards to requirements for soil moisture content and nutrient levels
Dillwynia tenuifolia	
Eucalyptus benthamii Camden White Gum	
Maundia triglochinoides	
Micromyrtus minutiflora	
Persicaria elatior Tall Knotweed	
Pterostylis saxicola Sydney Plains Greenhood	
Lower Risk threatened flora species	
Acacia bynoeana Bynoe's Wattle	Lower risk threatened flora species are those that occur in landscape positions where hydrological processes have a lower level of influence on edaphic conditions
Acacia pubescens Downy Wattle	
Epacris purpurascens var. *purpurascens*	
Grevillea juniperina subsp. *juniperina* Juniper-leaved Grevillea	
Grevillea parviflora subsp. *parviflora* Small-flower Grevillea	
Hibbertia fumana	
Hibbertia puberula	

Relevant species/TECs	Use and importance of habitat type
Marsdenia viridiflora subsp. *viridiflora* Native Pear	
Melaleuca deanei Deane's Paperbark	
Persoonia bargoensis Bargo Geebung	
Persoonia nutans Nodding Geebung	
Pimelea curviflora var. *curviflora*	
Pimelea spicata Spiked Rice-flower	
Pomaderris brunnea Brown Pomaderris	
Pultenaea parviflora	
Pultenaea pedunculata Matted Bush-pea	
Higher Risk threatened fauna species	
Botaurus poiciloptilus Australasian Bittern	Higher risk threatened fauna species are those that are reliant on wetlands, lower Strahler order watercourses and riparian corridors, or soaks and fringing macrophyte vegetation for key aspects of their lifecycle
Ephippiorhynchus asiaticus Black-necked Stork	
Epthianura albifrons White-fronted Chat	
Heleioporus australiacus Giant Burrowing Frog	
Irediparra gallinacean Comb-crested Jacana	
Ixobrychus flavicollis Black Bittern	
Litoria aurea Green and Golden Bell Frog	
Myotis macropus Southern Myotis	
Pseudophryne australis Red-crowned Toadlet	
Rostratula australis Australian Painted Snipe	
Stictonetta naevosa Freckled Duck	
Lower Risk threatened fauna species	
Remaining candidate species and ecosystem credit fauna species	Lower risk threatened fauna species are those not directly reliant on waterbodies or wetlands, those associated with riparian corridors of higher Strahler watercourses, or those species within limited habitat within the nominated areas (such as waders)

24.11.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

WATER BODIES

Water bodies comprise non-vegetated wetlands, ponds, rivers, creeks, and other bodies of water, including farm dams, greater than 3 m wide. Water bodies occur in all nominated areas and were identified using the Digital Topographic Database hydro area layer (LPI, 2016).

Direct impacts on Southern Myotis and Green and Golden Bell Frog associated with waterbodies were determined by:

- Intersecting the hydro area layer with the species maps for these three species (see Chapter 11)

- Excluding water bodies that were within native vegetation based on the native vegetation map (see Chapter 11) (direct impacts to these water bodies are assessed through impacts to native vegetation and habitat (see Chapter 23)
- Intersecting water bodies with species habitat that occurs within urban capable lands and transport corridors

The location of water bodies is shown in Map 24-4.

HYDROLOGICAL PROCESSES

Potential areas of hydrological change were mapped across the nominated areas using topographical features such as watercourses and changes in relief through the landscape to determine catchment areas and floodplains.

A digital elevation model was used to help visualise these catchment areas and floodplains and highlight those where development is to occur either within the floodplain or near the top of catchments, which were then mapped.

These mapped areas cover the land outside the urban capable land and transport corridors where it is expected that indirect impacts to species and TECs may occur as a result of the development changing the existing hydrological processes that currently support those ecological values.

Table 24-23 provides details of the areas considered to potentially undergo hydrological changes related to development either in the upper reaches of the water catchment area, or development on a floodplain. These mapped areas are shown on Map 24-4 and are considered to cover the extent of potential hydrological change which may occur as a result of adjacent development within the nominated areas.

Table 24-23: Areas of potential hydrological impacts

Nominated area	Location	Type
Wilton	Allens Creek catchment	Development in catchment area modifying feeder creeks
	Allens Creek tributary catchment	Development in catchment area modifying feeder creeks
	Byrnes Creek catchment	Development in area surrounding catchment
	Nepean River catchment	Development in catchment area modifying feeder creeks
	Stringybark Creek catchment	Development in catchment area modifying feeder creeks
GMAC	Cataract/Elladale/Nepean catchment	Development in upper catchment area modifying feeder creeks
	Cataract/Rocky Ponds catchment	Development in upper catchment area modifying feeder creeks
	Elladale Creek catchment	Development in upper catchment area surrounding watercourses and modifying feeder creeks
	Elladale/Nepean catchment	Development in upper catchment area modifying feeder creeks
	Menangle/Woodhouse/Leafs catchment	Development in upper catchment area modifying feeder creeks
	Nepean River catchment	Development in upper catchment area modifying feeder creeks
	Ousedale Creek catchment	Development in upper catchment area surrounding watercourse and modifying feeder creeks
WSA	Badgerys Creek floodplain	Development on floodplain and within catchment area surrounding watercourse
	Cosgroves Creek floodplain	Development on all sides of floodplain and modification of feeder creeks

Nominated area	Location	Type
	Wianamatta (South Creek) and Kemps Creek floodplains	Development on floodplain and within catchment areas surrounding watercourse
	Wianamatta (South Creek) floodplain	Development on floodplain
GPEC	Wianamatta (South Creek) floodplain	Development on floodplain (major roadway development)
	Surveyors Creek tributary	Development in upper catchment area modifying feeder creeks

24.11.3 NATURE, EXTENT, AND DURATION OF RESIDUAL IMPACTS

WATER BODIES

Avoidance of impacts

Water bodies occur throughout each of the nominated areas and it was not possible to determine avoidance outcomes for water bodies. However, the urban capable land has avoided riparian corridors along waterways (see Chapter 4) that are likely to be preferred movement and foraging habitat for many of the species associated with water bodies. The Plan includes several specific mitigation measures to monitor impacts of hydrological changes to high-risk species and to avoid and minimise impacts to vegetation in riparian corridors (see Section 24.11.6).

Residual impacts

The nature, extent, and duration of the residual impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major infrastructure corridors on water bodies are set out in Table 24-24.

Table 24-24: Nature, extent, and duration of residual impacts –water bodies

Species/TEC	Nature	Extent	Duration
Green and Golden Bell Frog	**Direct impacts:** The development will directly impact three small waterbodies within the potential habitat area for this species	2.7 ha of water bodies in all nominated areas	Long-term
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Adjacent to urban capable land along Ropes Creek in GPEC	Temporary or long-term
Southern Myotis	**Direct impacts:** The development will directly impact approximately 1,000 waterbodies within suitable habitat for this species	786.5 ha of water bodies in all nominated areas	Long-term
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Water bodies adjacent to urban capable land in each nominated area	Temporary or long-term
White-bellied Sea-eagle	**Direct impacts:** The development will directly impact several waterbodies within suitable habitat for this species	Several water bodies within a total of 10 ha of suitable habitat that occurs in each nominated area. An impact of < 1 ha will occur	Long-term

Species/TEC	Nature	Extent	Duration
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Water bodies adjacent to urban capable lands in each nominated area	Temporary or long-term
Water birds	**Direct impacts:** The development will directly impact many waterbodies within suitable habitat for these species	Many water bodies scattered across each nominated area	Long-term
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Water bodies adjacent to urban capable lands in each nominated area	Temporary or long-term

HYDROLOGICAL PROCESSES

Avoidance of impacts

The steps taken to avoid and minimise impacts of the development in the nominated areas are set out in Chapter 14.

The urban capable land has avoided riparian corridors along waterways (see Chapter 14). This ensures the natural waterbodies providing the highest value potential habitat will be retained, and therefore minimising direct impacts to native species and vegetation dependent on those resources.

Development will occur in the upper catchment areas and on some floodplain catchment areas across the nominated areas. However indirect impacts will be avoided and minimised through incorporating best practice urban water management design into future developments (see Chapter 15 and Section 24.11.4).

Residual impacts

The nature, extent, and duration of the impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors on species on hydrological processes are set out in Table 24-25.

The figures presented in the table for the total extent of habitat has been calculated based on the total area of habitat for each group of ecological values (high/low risk species or TECs) within each nominated area. Where habitat overlaps between species in the same group of ecological value (high/low risk species or TECs) the overlaps are 'dissolved' and the habitat area is calculated only once. The total amount equates to an approximate area of habitat that could be utilised by multiple species or TECs within each group.

For lower risk fauna, which includes ecosystem credit species, all native vegetation mapped in the nominated areas was used as a surrogate for species habitat. This is considered suitable as all mapped native vegetation within the nominated areas is potential habitat for at least one ecosystem credit species.

The potential impact areas are those areas of each ecological value that are potentially subject to hydrological changes. These figures have been estimated and represent a worst case. It is unlikely that impacts would occur across all extents in the table, but rather are likely to be more localised within these larger areas.

Key areas potentially subject to impacts include:

- To higher risk fauna species in GPEC, where hydrological changes associated with development on floodplain (major transport corridors) may potentially impact on an area of habitat of 696 ha (or 27 per cent of total mapped non-certified habitat)
- To higher risk flora habitat in:
    - Wilton – 429 ha (or 46 per cent of total mapped non-certified habitat) associated with development modifying feeder creeks

- GMAC – 389 ha (or 46 per cent of total mapped non-certified habitat) associated with development in catchment area modifying feeder creeks
- GPEC – 382 ha (or 44 per cent of total mapped non-certified habitat) associated with development on floodplain (major transport corridor)

It should be noted that while impacts associated with hydrological processes described below and in Table 24-27 are predicted to potentially occur over relatively large areas of habitat and native vegetation, the potential for impacts occurring over the entire areas described is considered highly unlikely, with impacts much more likely to occur at a local scale. Therefore, the predicted extent of impacts is very conservative and comprise the total maximum areas within which impacts associated with altered hydrology could potentially occur rather than the area subject to likely impacts.

Table 24-25: Nature, extent, and duration of residual impacts – hydrological processes

Location	Nature	Species/TEC	Total non-certified extent in nominated areas (approx.) (ha)	Non-certified area where potential impacts could occur (approx.) (ha & %)	Duration
Wilton	Development in catchment area modifying feeder creeks	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1,154 • 90 • 942 • 1,799 • 1,085 • 1,718	• 434 (38%) • 16 (187%) • 429 (46%) • 656 (36%) • 438 (40%) • 652 (38%)	Long-term
	Development in area surrounding catchment	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1,154 • 90 • 942 • 1,799 • 1,085 • 1,718	• 57 (5%) • 10 (11%) • 72 (8%) • 92 (5%) • 70 (6%) • 91 (5%)	Long-term
GMAC	Development in catchment area modifying feeder creeks	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1,927 • 337 • 1,820 • 3,009 • 1,856 • 2,909	• 358 (19%) • 26 (8%) • 389 (21%) • 574 (19%) • 351 (19%) • 546 (19%)	Long-term
	Development in upper catchment area surrounding watercourses and modifying feeder creeks	• Higher risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1,927 • 1,820 • 3,009 • 1,856 • 2,909	• 122 (6%) • 129 (7%) • 133 (4%) • 78 (4%) • 133 (5%)	Long-term
WSA	Development on floodplain and within catchment area surrounding watercourse	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 277 • 162 • 187 • 508 • 378 • 465	• 96 (35%) • 7 (4%) • 52 (28%) • 100 (20%) • 121 (32%) • 104 (22%)	Long-term

Location	Nature	Species/TEC	Total non-certified extent in nominated areas (approx.) (ha)	Non-certified area where potential impacts could occur (approx.) (ha & %)	Duration
	Development on all sides of floodplain and modification of feeder creeks	• Higher risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 277 • 187 • 508 • 378 • 465	• 14 (5%) • 2 (1%) • 16 (3%) • 11 (3%) • 14 (3%)	Long-term
	Development on floodplain - avoided areas potentially impacted	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 277 • 162 • 187 • 508 • 378 • 465	• 3 (1%) • 14 (9%) • 6 (3%) • 18 (4%) • 12 (3%) • 17 (4%)	Long-term
GPEC	Development on floodplain - major roadway development	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1,003 • 1,647 • 874 • 3,437 • 2,564 • 2,887	• 548 (55%) • 347 (21%) • 382 (44%) • 993 (29%) • 696 (27%) • 1916 (66%)	Long-term
	Development in upper catchment area modifying feeder creeks	• Higher risk TECs • Lower risk TECs • Higher risk flora • Higher risk fauna • Lower risk fauna	• 1,003 • 874 • 3,437 • 2,564 • 2,887	• 7 (<1%) • 6 (<1%) • 7 (<1%) • 1 (<1%) • 7 (<1%)	Long-term

24.11.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

This section identifies commitments in the Plan relating to prescribed impacts and general mitigation measures/development controls that are commonly implemented by planning authorities through the development application process and are relevant to managing prescribed impacts. Specific mitigation measures that will apply to specific species and TECs in certain locations are identified in Section 24.11.6.

This section also summarises the processes to implement the general and specific mitigation measures/development controls for the different development types under the Plan. These processes are described in detail in Chapter 15.

URBAN AND INDUSTRIAL DEVELOPMENT AND INTENSIVE PLANT AGRICULTURE

The Plan includes a commitment (Commitment 5) to mitigate prescribed impacts from urban and industrial development and intensive plant agriculture on TECs, threatened species and their habitat within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Development Control Plans (DCPs) will be prepared for each nominated area that will include development controls to address prescribed impacts. The development controls in DCPs will be implemented through the standard development application process under the EP&A Act that occurs prior to development proceeding.

The Department has prepared a DCP template that provides model provisions to help ensure mitigation measures identified in the Plan to address prescribed impacts are incorporated into DCPs as development controls and are applied consistently across the nominated areas. The DCP template includes both:

- A common set of controls that apply across the nominated areas and inform general biodiversity protection. These controls are commonly implemented by planning authorities to manage prescribed impacts through the development application process – these are identified in Chapter 15 (Table 15-4 to Table 15-13)
- A specific set of controls that apply to specific species and TECs in certain locations. These controls have been identified through this Assessment Report and are needed to address the residual risks that remain after the common set of controls are applied. These are identified in Appendix E of the Plan

The common controls included in the DCP template relevant to managing prescribed impacts on species associated with hydrological processes and water quality, including (see Chapter 15, Section 15.6.1):

- Waterways: Maintain waterways of Strahler order 2 or higher in a natural state, including riparian corridors
- Water cycle management: Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
- Water quality: Stormwater systems must be constructed and maintained to achieve EES water quality targets
- Soil erosion and sedimentation: Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.1.

INFRASTRUCTURE AND MAJOR TRANSPORT CORRIDORS

Commitment 5 includes mitigating prescribed impacts of infrastructure within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Commitment 6 requires mitigating prescribed impacts of the major transport corridors in accordance with the:

- Major transport corridors class of action description, including the NSW State Significant Infrastructure (SSI) (or equivalent) approval for certified major transport corridors
- Specific mitigation measures to address impacts on biodiversity values prescribed in Appendix E of the Plan

Both infrastructure and the major transport corridors will be subject to future environmental assessment and approval processes under the EP&A Act based on detailed design at the time the projects are proposed (see Part 2).

For the major transport corridors, an action under Commitment 5 requires Transport for NSW to:

> *'Implement specific mitigation measures prescribed in Appendix E and identify and implement additional mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the SSI (or equivalent) approval process, as well as best practice guidelines, including the RMS Biodiversity Guidelines'*

This requirement ensures mitigation measures to address prescribed impacts on TECs and species associated with water bodies and hydrological processes are identified and implemented through or alongside the future environmental assessment process and based on detailed design of the project.

A detailed description of the processes to implement mitigation measures for infrastructure and the major transport corridors in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 (for infrastructure) and Section 15.6.3 (for the major transport corridors).

24.11.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

WATER BODIES

An assessment of the potential prescribed impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors in relation to water bodies is set out in Table 24-26. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-26: Assessment of potential prescribed impacts – water bodies

Relevant species/TECs	Assessment of potential prescribed impacts	Residual risk of impacts?
Green and Golden Bell Frog	Development under the Plan will impact three small waterbodies within potential habitat for the species. This habitat is known to have supported a population of Green and Golden Bell Frog, with 6 BioNet records made between 1998 and 2012 At the time of public exhibition, it was considered likely that the population at this locality could still be present, and targeted surveys of the site had not been completed. The draft Plan at this stage contained a species-specific measure to undertake surveys within potential habitat along Ropes Creek to determine if the species was still present, and if confirmed to be present, to avoid, protect and enhance key habitat features of the site. Targeted surveys of Ropes Creek have since been completed. The surveys were carried out in December 2020 and January 2021. The surveys did not find any individuals of the species present at the site. Potential shelter and dispersal habitat for the species was identified, yet the habitat of the locality was considered unlikely to be suitable for breeding (see Supporting Document I) Impacts are unlikely to cause population decline for this species at a local, regional, or State scale because the majority (greater than 95 %) of records for the species occur in the eastern third of the Cumberland subregion outside the nominated areas (Lemckert, 2019) and the nominated areas are unlikely to be important for species persistence	Unlikely
Southern Myotis	There is a low risk that direct impacts will cause population decline at a local level. The development will remove 328.4 ha of a total of 786.5 ha of water bodies within suitable habitat for this species in the nominated areas (approximately 41.8 % of water bodies within suitable habitat in the nominated areas). However, inspection of aerial photos suggests many of these water bodies are farm dams that are likely to provide more marginal foraging habitat for the species. Urban capable lands have avoided riparian corridors along waterways (see Chapter 14) that are likely to be preferred foraging habitat for the species. Furthermore, riparian corridors across the nominated areas have been avoided (see Chapter 14) and general mitigation measures will be put in place to further protect riparian corridors. It is also likely that urban landform water bodies will be created within developed lands, potentially providing some habitat Impacts are unlikely to cause population decline for this species at a regional or State scale because records for the species are widespread across the bioregion and NSW and the species does not appear to be highly reliant on the Cumberland subregion	Unlikely
White-bellied Sea Eagle	There is a low risk that direct impacts will cause population decline at a local, regional, or State scale because: • Most water bodies impacted by the development across the nominated areas are farm dams that do not provide suitable foraging habitat for the species • Only very small amounts of potential habitat for the species containing water bodies are being impacted relative to suitable habitat remaining in the subregion Furthermore, riparian corridors across the nominated areas have been avoided (see Chapter 14) and general mitigation measures will be put in place to further protect riparian corridors	Unlikely
Water birds	There is a low risk that direct impacts will cause population decline at a local, regional, or State scale because most water bodies impacted by the development across the nominated areas are farm dams that are likely to provide more marginal foraging habitat for most of these species, as they are generally associated with vegetated waterbodies Furthermore, riparian corridors across the nominated areas have been avoided (see Chapter 14) and generic mitigation measures will be put in place to further protect riparian corridors	Unlikely

HYDROLOGICAL PROCESSES

The risk and consequences of the impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors in relation to hydrological processes are set out in Table 24-27. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-27: Assessment of potential prescribed impacts – hydrological processes

Assessment of potential prescribed impacts	Relevant species/TECs	Residual risk of impacts?
Risks associated with development in upper catchment areas include: • An increase in impermeable areas may result in higher levels of fluctuation in overland flow patterns reaching downstream areas. Following rain events downstream areas are more likely to receive higher volumes of water at higher velocities, over a shorter period of time, leading to higher potential for erosion, changes in deposition and sedimentation patterns and changes to water quality and type and volume of nutrient load. Conversely, as less water is being absorbed by vegetated areas there is less water in the soil during drier times leading to longer periods with lower levels of water availability between rain events • Changes to overland flow patterns through channelisation of stormwater into creeks and stormwater management systems may directly impact upon populations of higher risk flora and fauna species and/or TECs downstream that are reliant on current hydrological patterns for survival • Increases in, or changes to, nutrients and pollutants in stormwater and run-off as a result of anthropogenic inputs such fertilisers, herbicides, soil conditioners, and petrol/oil	Higher risk species and TEC	Potentially
Risks associated with development on floodplains include: • Changes in flooding regimes and patterns resulting from construction and earthworks may alter the relief of floodplains. This can confine streamlines to channels and reduce the width of those channels, which results in increased water velocities and impacts on groundcover. Increased water velocity may also impact nutrient deposition reducing the nutrient input for floodplain dependent species and TECs • Changes to flooding regimes and patterns may directly impact populations of higher risk flora and fauna species and/or TECs downstream that are reliant on current hydrological patterns for survival. Changes may result in periodically wet areas being reduced or lost, or formerly drier areas becoming periodically inundated. This could substantially impact upon the vegetation present within the floodplain The general mitigation measures are considered adequate to manage these risks to lower risk species/TECs. The Plan includes specific mitigation measures to manage this risk for higher risk species and TECs	Lower risk species and TECs	Unlikely

24.11.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-28 identifies additional specific mitigation measures under the Plan to address residual risks due to the development. These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on the TECs.

Table 24-28: Specific mitigation measures – water bodies and hydrological processes

Relevant species	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
Higher risk species and TECs	• Actions under Commitment 5 specify that DCPs will be audited to ensure development controls are being	Urban, industrial and infrastructure development	There is a risk that development in water catchments and on

	incorporated in accordance with the Plan and effectively implemented. If monitoring finds that this is not the case, new controls will be reviewed and redrafted to ensure stronger consideration of the controls through council assessment processes • The Plan includes an action under Commitment 3 to ensure major transport corridors are designed to avoid and minimise impacts to vegetation in riparian corridors. As part of this commitment, the Plan will ensure OSO waterway crossings minimise structures within riparian corridors, waterway re-alignments, and bulk earthworks on adjacent floodplain areas	Major transport corridors	floodplains may result in residual localised impacts to high risk species and TECs. Auditing of DCPs to ensure development controls are being incorporated in accordance with the Plan and effectively implemented is considered to adequately reduce this risk

The specific measures will be implemented in the same way as the general mitigation measures as described above and in detail in Chapter 15, Sections 15.6.1, 15.6.2 and 15.6.3.

24.12 ASSESSMENT OF VEHICLE STRIKES

24.12.1 LIST OF RELEVANT SPECIES

Vehicle strikes have been identified as a key threat to several species known or predicted to occur in the nominated areas, including:

- Koala
- Green and Golden Bell Frog
- Eastern Pygmy-possum
- Spotted-tailed Quoll
- Yellow-bellied Glider
- Squirrel Glider
- Broad-headed Snake

24.12.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

The development will lead to new roads and an increase in the volume of vehicles on existing roads. The main risks areas associated with these impacts occur in areas of suitable habitat of species vulnerable to vehicle strikes where:

- New roads are built within areas of suitable habitat
- Existing roads occur within areas of suitable habitat, assuming that vehicle volumes will increase on these roads

Risk areas are described for each relevant species in Table 24-29.

24.12.3 LIKELIHOOD OF VEHICLE STRIKES WITHIN RISK AREAS

An analysis of the likelihood of vehicle strikes from traffic associated with urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors is set out in Table 24-29. The analysis was undertaken on the basis of:

- Likelihood of occurrence of species vulnerable to vehicle strikes, based on records
- Evidence of previous roadkill in the area for those species
- Consideration of relevant life history traits

Observation codes within BioNet records were interrogated to identify whether species records were associated with vehicle strikes (Observation Code R – Roadkill).

Table 24-29: Key risk areas and likelihood of vehicle strikes

Relevant species/TECs	Key risk areas	Likelihood of vehicle strikes in key risk areas
Koala	The key risk areas are where busy roads cut through, or are located adjacent to, areas of Koala habitat. Existing roadkill hotspots (where greater than four Koalas are killed within a 2 km stretch of road) are located in the following areas: • Picton Road between Cordeaux Dam and Wilton • Macarthur Drive • Eastern end of Wilton Road • Appin Road between Appin and Campbelltown • Hume Highway at the Bargo exit While the Plan does not propose new roads which cut through substantial areas of Koala habitat, the Plan includes significant areas of urban capable land adjacent to Koala habitat. This poses a risk of road mortality to Koalas who may venture out of Koala habitat into developed areas	The likelihood of vehicle strikes is considered to be high. Increased traffic density has been shown to increase the rate of vehicle strike. The Plan will result in significant areas of new development and without mitigation, the risk of vehicle strike to Koalas will increase substantially as development proceeds
Green and Golden Bell Frog	The key risk area occurs in the northern part of the GPEC, where many existing roads occur across a large patch of suitable habitat associated with a riparian corridor and the OSO intersects the edge of that habitat in Wianamatta Regional Park	The likelihood of vehicle strikes is difficult to predict but is considered to be low because: • Where the OSO intersects suitable habitat, this only occurs on the edges of suitable habitat and does not disrupt any existing movement corridors. This reduces the likelihood the species needs to cross the OSO to move between areas of suitable habitat. Recent targeted surveys at this location along Ropes Creek did not detect the species (see Supporting Document I) • Many existing roads occur within areas of suitable habitat. Despite this, there have been no recorded vehicle strikes on this species. This suggests this species may not be regularly needing to move across existing roads to disperse between areas of suitable habitat, or is able to pass under existing roads where road crossings provide suitable conditions
Eastern Pygmy-possum	The key risk areas occur:	The likelihood of vehicle strikes is considered to be low because:

Relevant species/TECs	Key risk areas	Likelihood of vehicle strikes in key risk areas
	• Northern part of Wilton and southern part of GMAC where urban capable lands and associated roads occur adjacent to suitable habitat • Central part of WSA where the OSO impacts small areas of suitable habitat mainly associated with riparian corridors • Northern and central part of GPEC where the OSO intersects suitable habitat in Wianamatta Regional Park and several riparian corridors	• Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers • The vast majority of suitable habitat for this species in Wilton and GMAC is restricted to the gorges and gullies mainly on the edges of the nominated areas. The urban capable lands generally occur outside these areas and no major roads directly cross these areas as part of the development
Spotted-tailed Quoll	The key risk areas occur: • Northern part of Wilton and southern part of GMAC where urban capable lands and associated roads occur adjacent to suitable habitat • Central part of WSA where the OSO impacts small areas of suitable habitat mainly associated with riparian corridors • Northern and central part of GPEC where the OSO intersects suitable habitat in Wianamatta Regional Park and several riparian corridors	The likelihood of vehicle strikes on the important population of the species near Wilton is difficult to predict but is considered low to moderate as: • The vast majority of suitable habitat for this species is restricted to the gorges and gullies of the edges of Wilton. These areas are outside the urban capable lands and there will be no new roads intersecting these areas as part of the development • Several existing roads occur within areas of suitable habitat. Despite this, there have been no recorded vehicle strikes on this species. This suggests this species may not be regularly needing to move across existing roads to disperse between areas of suitable habitat, or is able to pass under existing roads where road crossings provide suitable conditions The likelihood of vehicle strikes in the other nominated areas is considered to be low because: • Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers • Many existing roads occur within areas of suitable habitat. Despite this, there have been no recorded vehicle strikes on these species in the nominated areas
Yellow-bellied Glider Squirrel Glider Broad-headed Snake	The key risk areas occur in the northern part of Wilton and southern part of GMAC where urban capable lands and associated roads occur adjacent to suitable habitat	The likelihood of vehicle strikes is considered to be low because: • No records for these species occur in the nominated areas, except for two recent records of Squirrel Glider in the gorge areas in Wilton, and one record of Yellow-bellied Glider in GPEC, which suggests these species may occur only in small numbers

Relevant species/TECs	Key risk areas	Likelihood of vehicle strikes in key risk areas
		• The vast majority of suitable habitat for these species in Wilton and GMAC is restricted to the gorges and gullies mainly on the edges of the nominated areas. The urban capable lands generally occur outside these areas and no major roads directly cross these areas as part of the development
Broad-headed Snake	The key risk areas occur in the northern part of Wilton where urban capable lands and associated roads occur adjacent to suitable habitat	The likelihood of vehicle strikes is considered to be low because: • No records for this species occur in Wilton, which suggests this species may not occur • Suitable habitat for this species in Wilton is likely to be restricted to the gorges and gullies on the edges of the nominated area. The urban capable lands generally occur outside these areas and no major roads directly cross these areas as part of the development

24.12.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

This section identifies commitments in the Plan relating to prescribed impacts and general mitigation measures/development controls that are commonly implemented by planning authorities through the development application process and are relevant to managing prescribed impacts. Specific mitigation measures/development controls that will apply to specific species and TECs in certain locations are identified in Section 24.12.6.

This section also summarises the processes to implement the general and specific mitigation measures/development controls for the different development types under the Plan. These processes are described in detail in Chapter 15.

URBAN AND INDUSTRIAL DEVELOPMENT AND INTENSIVE PLANT AGRICULTURE

The Plan includes a commitment (Commitment 5) to mitigate prescribed impacts from urban and industrial development and intensive plant agriculture on TECs, threatened species and their habitat within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Development Control Plans (DCPs) will be prepared for each nominated area that will include development controls to address prescribed impacts. The development controls in DCPs will be implemented through the standard development application process under the EP&A Act that occurs prior to development proceeding.

The Department has prepared a DCP template that provides model provisions to help ensure mitigation measures identified in the Plan to address prescribed impacts are incorporated into DCPs as development controls and are applied consistently across the nominated areas. The DCP template includes both:

- A common set of controls that apply across the nominated areas and inform general biodiversity protection. These controls are commonly implemented by planning authorities to manage prescribed impacts through the development application process – these are identified in Chapter 15 (Table 15-4 to Table 15-13)
- A specific set of controls that apply to specific species and TECs in certain locations. These controls have been identified through this Assessment Report and are needed to address the residual risks that remain after the common set of controls are applied. These are identified in Appendix E of the Plan and Section 24.12.6 below

The common controls included in the DCP template relevant to managing prescribed impacts on species due to vehicle strike are:

- Implement traffic calming measures in development areas not subject to Koala exclusion fencing, including speed limit restrictions for areas adjacent to land with biodiversity values, and installation of wildlife signposting and speed humps and audible surfacing in accordance with relevant standards
- Install and maintain fauna-friendly road design structures in appropriate areas adjacent to fauna habitat, such as underpasses, fauna bridges and overpasses consistent with any approval conditions and the RMS Biodiversity Guidelines

The specific controls included in the DCP template are discussed in Section 24.12.6.

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

INFRASTRUCTURE AND MAJOR TRANSPORT CORRIDORS

Commitment 5 includes mitigating prescribed impacts of infrastructure within the nominated areas, including meeting specific mitigation requirements in accordance with Appendix E of the Plan.

Commitment 6 requires mitigating prescribed impacts of the major transport corridors in accordance with the:

- Major transport corridors class of action description, including the NSW State Significant Infrastructure (SSI) (or equivalent) approval for certified major transport corridors
- Specific mitigation measures to address impacts on biodiversity values prescribed in Appendix E of the Plan

Both infrastructure and the major transport corridors will be subject to future environmental assessment and approval processes under the EP&A Act based on detailed design at the time the projects are proposed (see Part 2).

The assessment of the prescribed impacts of infrastructure and the major transport corridors associated with vehicle strike in Section 24.12.5 led to the identification of several mitigation measures. These mitigation measures are identified in Appendix E of the Plan and Section 24.12.6 below.

To ensure implementation of these mitigation measures for infrastructure, the Department will prepare a guideline under clause 228 of the EP&A Regulation – the Cumberland Plain Conservation Plan Guidelines for Infrastructure Development. The infrastructure guideline must be taken into account when public authorities consider the likely impact of infrastructure on the environment under the EP&A Act through the future environmental assessment process. The mitigation measures identified in Section 24.12.6 to address prescribed impacts associated with vehicle strike will be incorporated into the infrastructure guideline.

For the major transport corridors, an action under Commitment 5 requires Transport for NSW to:

> *'Implement specific mitigation measures prescribed in Appendix E and identify and implement additional mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with the SSI (or equivalent) approval process, as well as best practice guidelines, including the RMS Biodiversity Guidelines'*

This requirement ensures the mitigation measures identified in Section 24.12.6 to address prescribed impacts associated with vehicle strike are implemented through or alongside the future environmental assessment process and based on detailed design of the project.

A detailed description of the processes to implement mitigation measures for infrastructure and the major transport corridors in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 (for infrastructure) and Section 15.6.3 (for the major transport corridors).

24.12.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

An assessment of the potential prescribed impacts from urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors in relation to vehicle strikes is set out in Table 24-30. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-30: Risks and consequences of impacts – vehicle strike

Relevant species/TECs	Assessment of the potential prescribed impacts	Residual risk of impact
Koala	Without sufficient species-specific mitigation, there is a high risk that impacts may cause population decline at a local level. The Plan will lead to increased traffic on existing roads within or adjacent to habitat areas occupied by the Southern Sydney Koala population. The Plan include species-specific mitigation measures to address this risk	Yes

Relevant species/TECs	Assessment of the potential prescribed impacts	Residual risk of impact
Green and Golden Bell Frog	There is a low risk impacts may cause population decline at a local level. The species may occur in GPEC, and while the development will only intersect the edges of suitable habitat and existing roads already occur in the vicinity of suitable habitat, the development will lead to increased traffic levels on existing roads Impacts are unlikely to cause population decline for this species at a regional or State scale because the majority (greater than 95 %) of records for the species occur in the eastern third of the Cumberland subregion outside the nominated areas (Lemckert, 2019) and the nominated areas are unlikely to be important for species persistence The general mitigation measures are considered adequate to reduce this risk The Plan also includes a specific mitigation measure for the transport corridors that may also benefit this species in the northern part of GPEC	Unlikely
Eastern Pygmy Possum	Impacts are unlikely to cause population decline for this species at a local, regional, or State scale because: • The likelihood of vehicle strikes in key risk areas is considered to be low • Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers While risks are considered unlikely, the Plan includes: • General mitigation measures to reduce any actual risk • A specific mitigation measure for the transport corridors that may benefit this species in WSA and GPEC	Unlikely
Spotted-tailed Quoll	There is a low to moderate risk impacts may cause population decline at a local level. An important population of the species occurs immediately to the south of Wilton. While no new major roads will intersect suitable habitat in this area, the development will lead to increased traffic levels on existing roads. Impacts are unlikely to cause population decline for this species at a regional or State scale because: • The vast majority of suitable habitat for this species, including in Wilton and the other nominated areas, are outside the urban capable lands • Few records occur within or in the vicinity of the other nominated areas, which suggests this species may not occur in the area or occurs only in small numbers • There have been no recorded vehicle strikes on this species in the nominated areas suggesting this species may not be regularly needing to move across existing roads to disperse between areas of suitable habitat The general mitigation measures are considered adequate to reduce this risk The Plan also includes a specific mitigation measure for the transport corridors that may also benefit this species in WSA and GPEC	Unlikely

Relevant species/TECs	Assessment of the potential prescribed impacts	Residual risk of impact
Yellow-bellied Glider Squirrel Glider	Impacts are unlikely to cause population decline for this species at a local, regional, or State scale because: • The risk of vehicle strike in key risk areas is considered to be low • Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers While risks are considered unlikely, the Plan includes: • General mitigation measures to reduce any actual risk • A specific mitigation measure for the transport corridors that may benefit this species in WSA and GPEC	Unlikely
Broad-headed Snake	Impacts are unlikely to cause population decline for this species at a local, regional, or State scale because: • The risk of vehicle strike in key risk areas is considered to be low • No records occur within or in the vicinity of the Wilton (and the other nominated areas), which suggests this species may not occur in the area	Unlikely

24.12.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-31 identifies additional specific mitigation measures under the Plan to address residual risks due to the development.

Many areas of suitable habitat for Koala overlap with suitable habitat for other species susceptible to vehicle strikes, such as Spotted-tailed Quoll, Eastern Pygmy Possum, and Yellow-bellied Glider, and the specific mitigation measures for Koala are likely to benefit these other species in many cases.

These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on these species.

Table 24-31: Specific mitigation measures – vehicle strikes

Relevant species/TECs	Specific mitigation measure	Applicable development	Uncertainty or risks of failure

Koala	A range of mitigation measures including:
	• Commitment 7, which involves installing exclusion fencing:
	  ○ Between Koala habitat and urban capable land
	  ○ Along both sides of Appin Road
	• A range of measures in Appendix E of the Plan including:
	  ○ Development controls to reduce traffic mortality in areas where exclusion fencing is not feasible
	  ○ A measure to ensure roads constructed as essential infrastructure do not pose a threat of roadkill to Koalas
		Urban and industrial development, and infrastructure (including essential infrastructure)	There are inherent uncertainties with regards to measures to protect Koalas from road mortality (such as success of exclusion fences in preventing Koala movement, for instance if fences become damaged in the future). However, protection of Koalas is a key focus of the Plan, and ongoing monitoring and review of both the Plan's implementation and the local Koala population means that any future potential issues will be identified and addressed as part of the Plan's MER and adaptive management

Relevant species/TECs	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
			framework. As a result, the risk of failure is considered to be low
Green and Golden Bell Frog Yellow-bellied Glider Squirrel Glider Eastern Pygmy Possum Spotted-tailed Quoll	The Plan includes a commitment to ensure certified-major transport corridors are designed to avoid areas of potential habitat connectivity within riparian corridors where possible for these species (Commitment 3). This is expected to reduce the risk of vehicle strike in these areas	Major transport corridors	Exact outcomes not possible to predict, however, the commitment is expected to reduce the risk of vehicle strike

The specific measures will be implemented in the same way as the general mitigation measures as described above and in detail in Chapter 15, Sections 15.6.1 and 15.6.2.

25 Serious and irreversible impacts

25.1 INTRODUCTION

Section 10.2 of the BAM requires the BCAR to assess whether the urban and industrial development, infrastructure, intensive plant agriculture, and major transport corridors in the nominated areas will result in serious and irreversible impacts (SAII) to any NSW listed TECs or species. As outlined in the *Guidance to assist a decision-maker to determine a serious and irreversible impact* (DPIE, 2019) an SAII is one that:

- *Will cause a further decline of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to be in a rapid rate of decline, or*
- *Will further reduce the population size of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very small population size, or*
- *Impact on the habitat of a species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very limited geographic distribution, or*
- *Impact on a species or ecological community that is unlikely to respond to measures to improve habitat and vegetation integrity and is therefore irreplaceable*

This section:

- Sets out the approach and results for identifying relevant TECs and species that are potentially subject to serious and irreversible impacts due to the development (SAII entities)
- Provides a detailed assessment for each relevant SAII entity

Impacts to SAII entities were assessed in accordance with the requirements of Section 10.2 of the BAM and Appendix 4 of the DPIE guidelines (DPIE, 2019). The structure of the assessment for each SAII entity in sections 25.3 to 25.14 reflects these requirements.

25.2 IDENTIFYING SAII ENTITIES

25.2.1 APPROACH

The approach to identify SAII entities impacted by the development is described in Chapter 12 and involved:

- Comparing the list of NSW listed TECs and ECS and candidate SCS that occurs within the nominated areas and are potentially impacted by the development with the:
  - List of SAII entities in the DPIE guidelines (DPIE, 2019)
  - Threatened Biodiversity Data Collection (TBDC) that indicates whether a TEC or species is an SAII entity
- Determining whether any other NSW listed TECs or ECS and candidate SCS that occur within the nominated areas have the potential to become an SAII in accordance with the requirement of section 10.2.1.4 of the BAM. This section of the BAM requires an assessment against the DPIE guidelines (DPIE, 2019) that includes four principles under the BC Regulation (see Table 25-1) that determine whether a species or TEC should be considered an SAII entity. This was undertaken by senior ecologists at Biosis by:
  - Undertaking a literature review to ascertain:
    - Distribution, including geographic extent and area of occupancy
    - Known or inferred reductions in geographic extent or area of occupancy
    - Population sizes and current knowledge of declining populations
    - Susceptibility to known threats, such as invasive weeds and pests, disease, or pathogens
    - Life history traits that may make the species particularly vulnerable
  - Investigating existing records and new records found during targeted surveys for this project and the updated native vegetation mapping (see Chapter 11), and using aerial imagery interpretation, to consider likely impacts in areas approved or planned for other future development in the region
  - Considering risk weightings in the TBDC

- Considering levels of existing protection
- Consultation with senior Department biodiversity officers

Table 25-1 summarises the principles under the BC Regulation that determine whether a species or TEC should be considered an SAII entity.

Table 25-1: Summary of serious and irreversible impact principles (DPIE, 2019)

Principle	Description

Principle 1	**Species or ecological community currently in a rapid rate of decline**
	Entities listed as critically endangered under the BC Act
	• The principle would generally capture entities listed as critically endangered under the BC Act where the reason for that listing is a very large reduction in population size
	Rapid rate of decline for species considered to be critically endangered by IUCN
	• The species has an observed, estimated, inferred, suspected, or projected population reduction of ≥80% in 10 years or three generations (whichever is longer).
	Rapid rate of decline for an ecological community considered to be critically endangered by IUCN
	• To be considered under this principle, the ecological community should have been observed, estimated, inferred, or reasonably suspected to have undergone, or be projected to undergo, a very large reduction in distribution, being:
	  ○ ≥ 90 % reduction where the reduction is measured since 1750 (historical decline), or
	  ○ ≥ 80 % reduction where the reduction is over a 50-year period, either in the past, future, or any part of the past, present, and future

Principle 2	**Species or ecological communities with a very small population size**
	Entities listed as critically endangered under the BC Act
	• The principle would generally capture species or ecological communities listed as critically endangered under the BC Act where the reason for that listing is a very small size or very high environmental degradation and/or a very large disruption of biotic processes or interactions, respectively
	Very small population size for species considered to be critically endangered by IUCN
	• Species that have a very small population size are species with a known population size that is either:
	  ○ fewer than 50 mature individuals independent of whether there are any threats, or
	  ○ fewer than 250 mature individuals and the species has an observed, estimated, or projected continuing decline:
	  ▪ of at least 25 % in three years or one generation (whichever is longer) OR
	  ▪ where the number of mature individuals in each subpopulation is < 50 OR
	  ▪ the percentage of mature individuals in one subpopulation is 90–100 % OR
	  ▪ the population is subject to extreme fluctuations in the number of individuals (IUCN, 2017)
	Very high environmental degradation or disruption of biotic processes or interactions for an ecological community considered to be critically endangered by IUCN
	• Ecological communities that are considered to have a very large degree of environmental degradation or disruption of biotic processes or interactions are those with:
	  ○ ≥ 90 % extent and severity where the disruption or impacts are measured since 1970
	  ○ ≥ 80 % extent and severity where the disruption or impacts are over a 50-year period, either in the past, future, or any part of the past, present, and future (as per (Bland *et al.*, 2016))

Principle	Description
Principle 3	**Species or area of ecological community with very limited geographic distribution** Entities listed as critically endangered under the BC Act • The principle would generally capture entities that are listed as critically endangered under the BC Act where the reason for that listing is their very highly restricted geographic distribution Very limited geographic distribution for species considered to be critically endangered by IUCN • Species that have a very limited geographic distribution are generally known to: o have an area of occupancy (sensu (IUCN, 2017)) of ≤ 10 km2 o have an extent of occurrence (sensu (IUCN, 2017)) of ≤ 100 km2 o have at least two of the following three conditions: ▪ are severely fragmented or only known from one location ▪ continuing decline ▪ extreme fluctuations o inhabit less than or equal to three locations in NSW Very limited geographic distribution for an ecological community considered to be critically endangered by IUCN • The geographical distribution of ecological communities is defined by the area of occupancy (sensu (Bland *et al.*, 2016)). Ecological communities with a very limited geographic distribution have an area of occupancy of less than or equal to two 10 x 10 km grid cells or an extent of occurrence of ≤ 1000 km2 (sensu (Bland *et al.*, 2016)) and one of the following: o an observed or inferred continuing decline in: ▪ a measure of spatial extent appropriate to the ecological community ▪ a measure of environmental quality appropriate to characteristic biota of the ecological community ▪ a measure of disruption to biotic interactions appropriate to the characteristic biota of the ecological community o observed or inferred threatening processes that are likely to cause continuing declines in geographic distribution, environmental quality, or biotic interactions within the next 20 years o an ecological community exists at one location
Principle 4	**Species or ecological community that is unlikely to respond to management and is therefore irreplaceable** • These are species or ecological communities with: 1. Life history traits and/or ecology which is known, but the ability to control key threats at the site scale is negligible. In general, these are species significantly threatened by uncontrollable disease (e.g. frogs highly threatened by chytrid fungus) 2. Known reproductive characteristics that severely limit their ability to increase the existing population on, or occupy new habitat at, a stewardship site. In general, these are plants that are sterile or largely clonal with no or very limited capacity to increase in number through seed production and recruitment • Irreplaceable o Whether an impact on an entity is considered irreplaceable takes into account two factors. The first factor is the likely success in achieving gain in condition, abundance, or habitat area. For potential species that are identified in criteria 1 and 2 above, the likelihood of achieving an offset gain is extremely low or highly uncertain

25.2.2 RESULTS

Table 25-2 and Table 25-3 identify the NSW listed TECs and ECS and candidate SCS species that are SAII entities and that are potentially directly or indirectly impacted by the development (highlighted in blue). These are:

- Cooks River/Castlereagh Ironbark Forest
- Cumberland Plain Woodland
- Shale Sandstone Transition Forest
- *Allocasuarina glareicola*
- *Chalinolobus dwyeri (*Large-eared Pied Bat)
- *Hibbertia fumana*
- *Lathamus discolor* (Swift Parrot)
- *Litoria aurea* (Green and Golden Bell Frog)
- *Melaleuca deanei*
- *Micromyrtus minutiflora*
- Raptors - *Haliaeetus leucogaster* (White-bellied Sea-Eagle), *Hieraaetus morphnoides* (Little Eagle), and *Lophoictinia isura* (Square-tailed Kite)
- *Pseudophryne australis* (Red-crowned Toadlet)

A TEC or species is an SAII entity either because:

- It is identified in the DPIE guidelines (DPIE, 2019) or TBDC as an SAII entity, or
- It has been assessed as meeting one or more of the four SAII principles in the BC Regulation (section 10.2.1.4 of BAM)

The species assessed under BAM as meeting one or more of the four SAII principles in the BC Regulation were:

- Green and Golden Bell Frog and Red-crown Toadlet – these species are likely to meet SAII Principle 4 because of their very high susceptibility to the disease Chytrid fungus
- *Micromyrtus minutiflora* – this species is likely to meet SAII Principle 3 because of its very highly restricted distribution and the development directly impacting potential habitat
- Three raptor species – White-bellied Sea-Eagle, Little Eagle, and Square-tailed Kite – these species are likely to meet SAII Principle 4 because there is potential for the development to impact breeding habitat for the species (hollows of very old trees) that cannot readily be created at a stewardship site

TECs and species were identified as unlikely to trigger SAII principles generally on the basis that the development will not have significant impacts on the TEC or species, and:

- The TEC or species has a relatively broad distribution across the Cumberland subregion or NSW
- Known populations for species are relatively large (> 250 individuals)

In considering the impacts to each TEC and species, both direct impacts on potential habitat for TECs and species (see Chapter 23) and existing and new records based on targeted surveys for this project, were taken into account.

Each SAII entity impacted by the development is assessed below in accordance with Section 10.2 of the BAM.

Table 25-2: Identification of TEC SAII entities and assessment against SAII principles

TEC name	NSW status	Cth status	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Castlereagh Scribbly Gum Woodland	V	E	No	No – unlikely to trigger SAII principles	N/A	No
Cooks River/Castlereagh Ironbark Forest	E	CE	SAII advice on EES website	N/A	Yes – directly impacted	Yes
Cumberland Plain Woodland	CE	CE	SAII advice on EES website	N/A	Yes – directly impacted	Yes
Freshwater Wetlands on Coastal Floodplains	E	-	No	No – unlikely to trigger SAII principles	N/A	No
Moist Shale Woodland	E	CE	No	No – unlikely to trigger SAII principles	N/A	No
River-flat Eucalypt Forest on Coastal Floodplains	E	-	No	No – unlikely to trigger SAII principles	N/A	No
Shale Gravel Transition Forest	E	CE	No	No – unlikely to trigger SAII principles	N/A	No
Shale Sandstone Transition Forest	CE	CE	SAII advice on EES website	N/A	Yes – directly impacted	Yes
Swamp Oak Floodplain Forest	E	E	No	No – unlikely to trigger SAII principles	N/A	No

Table 25-3: Identification of species SAII entities and assessment against SAII principles

Species name	NSW status	Cth status	Species type	Bio. risk weight.	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Acacia bynoeana	E	V	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Acacia pubescens	V	V	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Allocasuarina glareicola	E	E	SCS	3	SAII advice on EES website	N/A	Yes – potential habitat directly impacted	Yes
Anthochaera Phrygia^	CE	CE	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Anthochaera Phrygia**	CE	CE	SCS	3	No	No – unlikely to trigger SAII principles	No. This species is an SAII entity for mapped Important Areas. EES advised that no mapped Important Areas occur in the nominated areas	No
Artamus cyanopterus cyanopterus	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Botaurus poiciloptilus	E	E	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Calidris ferruginea^	E	CE	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Callocephalon fimbriatum**	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Callocephalon fimbriatum^	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Calyptorhynchus lathami**	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Calyptorhynchus lathami^	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No

Species name	NSW status	Cth status	Species type	Bio. risk weight.	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Cercartetus nanus	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Chalinolobus dwyeri	V	V	SCS	3	SAII advice on EES website	N/A	Yes – Habitat within 100 metres of potential breeding habitat (sandstone cliffs) will be directly impacted	Yes
Chthonicola sagittata	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Circus assimilis	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Climacteris picumnus victoriae	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Daphoenositta chrysoptera	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Dasyurus maculatus	V	E	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Dillwynia tenuifolia	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Epacris purpurascens var. *purpurascens*	V	-	SCS	1.5	No	No – unlikely to trigger SAII principles	N/A	No
Ephippiorhynchus asiaticus	E	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Epthianura albifrons	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Eucalyptus benthamii	V	V	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Falsistrellus tasmaniensis	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No

Species name	NSW status	Cth status	Species type	Bio. risk weight.	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Glossopsitta pusilla	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Grantiella picta	V	V	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Grevillea juniperina subsp. *juniperina*	V	-	SCS	1.5	No	No – unlikely to trigger SAII principles	N/A	No
Grevillea parviflora subsp. *parviflora*	V	V	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
*Haliaeetus leucogaster**	V	-	SCS	2	No	Yes – likely to trigger SAII principle 4	Yes – potential breeding habitat directly impacted	Yes
*Haliaeetus leucogaster^*	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Heleioporus australiacus	V	V	SCS	1.5	No	No – unlikely to trigger SAII principles	N/A	No
Hibbertia fumana	CE	-	SCS	3	SAII advice on EES website	N/A	Yes – potential habitat directly impacted	Yes
Hibbertia puberula	E	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
*Hieraaetus morphnoides**	V	-	SCS	1.5	No	Yes – likely to trigger SAII principle 4	Yes – potential breeding habitat directly impacted	Yes
*Hieraaetus morphnoides^*	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Hirundapus caudacutus	-	V	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Irediparra gallinacea	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No

Species name	NSW status	Cth status	Species type	Bio. risk weight.	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Ixobrychus flavicollis	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Lathamus discolor^	E	CE	ECS		No	N/A	N/A	Yes
Lathamus discolor	E	CE	SCS		SAII advice on EES website	N/A	SAII threshold applies - this species is an SAII entity for mapped important areas. Mapped important areas are directly impacted	Yes
Limicola falcinellus^	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Limosa limosa^	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Litoria aurea	E	V	SCS	2	No	Yes – likely to trigger SAII principles 1 and 4	Yes – potential habitat directly impacted	Yes
*Lophoictinia isura**	V	-	SCS	1.5	No	No – unlikely to trigger SAII principles	Yes – potential breeding habitat directly impacted	Yes
Lophoictinia isura^	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Marsdenia viridiflora subsp. *viridiflora*	E	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Maundia triglochinoides	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Melaleuca deanei	V	V	SCS	2	SAII advice on EES website	N/A	Yes – potential habitat directly impacted	Yes
Melanodryas cucullata cucullata	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No

Species name	NSW status	Cth status	Species type	Bio. risk weight.	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Melithreptus gularis gularis	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Meridolum corneovirens	E	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Micromyrtus minutiflora	E	V	SCS	2	No	Yes – likely to trigger SAII principle 3	Yes – potential habitat directly impacted	Yes
Micronomus norfolkensis	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Miniopterus australis^*	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Miniopterus orianae oceanensis^*	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
Myotis macropus	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Neophema pulchella	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Ninox connivens**	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
*Ninox connivens^*	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Ninox strenua**	V	-	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
*Ninox strenua^*	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No
*Pandion cristatus^*	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No

Species name	NSW status	Cth status	Species type	Bio. risk weight.	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Persicaria elatior	V	V	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Persoonia bargoensis	E	V	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Persoonia nutans	E	E	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No
Petaurus australis	V	-	ECS		No	No – unlikely to trigger SAII principles	N/A	No

25.3 COOKS RIVER/CASTLEREAGH IRONBARK FOREST

25.3.1 TEC BACKGROUND

Cooks River Castlereagh Ironbark Forest in the Sydney Basin Bioregion (CRCIF) is a dry sclerophyll open forest to low woodland community with an overstorey dominated by *Eucalyptus fibrosa* and *Melaleuca decora*, with *Eucalyptus longifolia* often present. The midstorey is usually moderate to dense, commonly including *Melaleuca nodosa* and *Lissanthe strigosa*, and to a lesser extent *Melaleuca decora*. The ground layer is generally sparse (OEH, 2019b).

The TEC is equivalent to the ecological community with the same name listed under the EPBC Act (DoE, 2015).

CRCIF primarily occurs in elevations below 100 m above sea level with mean annual rainfall of approximately 700-1,000 mm. It generally occurs on clay soils derived from Tertiary alluvium and on Wianamatta Shale soils found next to Tertiary alluvium. In the eastern areas of its distribution, the TEC can be found on soils with a sandstone influence (DoE, 2015). The TEC can intergrade into Shale-Gravel Transition Forest (where the alluvium is shallow), Castlereagh Swamp Woodland (in moist depressions) and Castlereagh Scribbly Gum Woodland (on sandier soils) (OEH, 2019b).

A range of fauna species occur in CRCIF, including reptiles, amphibians, birds, micro-bats, and marsupials. Most of these species also rely on other native vegetation in the Cumberland subregion (DoE, 2015). Most plant species in the TEC are able to regenerate after fire from lignotubers and buds beneath the bark and seeds stored in the soil (DoE, 2015).

CRCIF is confined to the Sydney Basin Bioregion and mostly restricted to the Cumberland subregion. The majority of the TEC is found in larger patches in the north-west part of the subregion in the Castlereagh area between Penrith and Richmond. Other significant patches occur in the Kemps Creek and Holsworthy areas. Smaller patches of the ecological community occur in the eastern part of the subregion, such as the upper Cooks River Valley (OEH, 2019b).

25.3.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

CRCIF has been identified as a potential serious and irreversible impacts entity based on advice from EES to accredited assessors in January 2019 as it has a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (OEH, 2017g).

CRCIF is associated with PCT 725 – 'Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion'. The TEC has been mapped within the nominated areas and the Cumberland subregion on the basis of the extent and condition of this PCT (see Chapter 11).

25.3.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of CRCIF in relation to the subject land is shown in Map 25-1.

The majority of CRCIF within the Cumberland subregion occurs outside the nominated areas within the Londonderry and Castlereagh areas in the northern part of the subregion.

The TEC has been mapped as occurring in the following nominated areas:

- GPEC
- WSA

The main occurrences of the TEC within these nominated areas are located:

- Within Wianamatta Regional Park in the northern part of GPEC
- In the south-eastern part of WSA

25.3.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.2 of the BAM.

10.2.2.1(A) THE ACTION AND MEASURES TAKEN TO AVOID THE DIRECT AND INDIRECT IMPACT ON THE POTENTIAL ENTITY FOR AN SAII

Avoidance and minimisation of impacts to biodiversity values, including CRCIF, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The baseline mapping for this assessment has mapped 63.4 ha of CRCIF within the nominated areas (not including excluded lands). Approximately 25.8 ha (40.7 per cent) of this was avoided within the nominated areas as part of the design of the urban capable land and transport corridors (not including excluded lands). Almost all of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 25-4.

The table shows that the majority of the total avoidance that has occurred (73.1 per cent) has been of CRCIF in intact condition, and that of the 35 ha of intact condition CRCIF (without excluded lands), the majority (18.9 ha or 54.2 per cent) has been avoided.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-4 shows the amounts of habitat within excluded lands for context only.

Table 25-4: Avoidance outcomes for Cooks River Castlereagh Ironbark Forest (PCT 725)

Condition	Total area in nominated areas (ha)	Area in excluded lands (ha)	Area without excluded lands (ha)	Directly impacted (ha)	Avoided for biodiversity purposes (ha)	Avoided for other purposes (ha)	Total avoidance (ha)
Intact	107.2	72.4	34.9	16.0	18.9	<0.1	18.9
Thinned	49.6	24.0	25.6	18.7	6.8	0.1	6.9
Scattered trees	9.5	6.5	3.0	2.9	<0.1	0.0	<0.1
Total	**166.3**	**102.9**	**63.4**	**37.6**	**25.7**	**0.2**	**25.8**

Avoidance of indirect impacts

Potential indirect impacts to CRCIF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(B) THE AREA (HA) AND CONDITION OF THE TEC TO BE IMPACTED DIRECTLY AND INDIRECTLY BY THE DEVELOPMENT

Direct impacts

A total of 37.6 ha of CRCIF will be directly impacted by the development. This is approximately half of the TEC in the nominated areas (without excluded lands). The direct impacts of the development are mainly associated with the transport corridors.

The main direct impacts occur:

- In the northern part of GPEC within Wianamatta Regional Park associated with the OSO
- In the south-eastern part of WSA associated with urban development

Scattered smaller patches of the TEC will also be directly impacted in the central part of GPEC.

The direct impacts of the development on CRCIF are provided in Table 25-5.

Table 25-5: Direct impacts on Cooks River Castlereagh Ironbark Forest (PCT 725)

PCT	Condition	Direct impacts (ha)						Vegetation integrity score
		Wilton*	GMAC*	WSA*	GPEC*	Transport #	Total	
725	Intact	0.0	0.0	0.8	0.0	15.2	**16.0**	49.2
725	Thinned	0.0	0.0	8.6	6.4	3.7	**18.7**	43.3
725	Scattered Trees	0.0	0.0	2.9	0.0	0.0	**2.9**	19.6
Total		**0.0**	**0.0**	**12.4**	**6.4**	**18.9**	**37.6**	

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Indirect impacts

Potential indirect impacts to CRCIF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(c) THE EXTENT TO WHICH THE IMPACT EXCEEDS THE THRESHOLD FOR THE POTENTIAL ENTITY

No threshold has been established for CRCIF.

10.2.2.1(d) THE EXTENT AND OVERALL CONDITION OF THE POTENTIAL TEC WITHIN AN AREA OF 1,000 HA, AND THEN 10,000 HA, SURROUNDING THE URBAN CAPABLE LANDS

The extent and condition of CRCIF surrounding the urban capable lands are provided in Table 25-6. Due to the scale of the development, calculations were also presented based on a 1 km buffer and a 10 km buffer from the outer edge of the urban capable lands, as well as buffers of 1,000 ha or 10,000 ha as per the BAM.

Table 25-6: Extent and condition of Cooks River Castlereagh Ironbark Forest (PCT 725) surrounding the urban capable lands

PCT	Condition	Area in 1,000 ha buffer	Area in 10,000 ha buffer	Area in 1,000 m buffer	Area in 10,000 m buffer
725	Intact	19.7	83.6	162.4	769.2
725	Thinned	21.4	30.9	46.7	117.2
725	Scattered Trees	3.6	6.8	17.6	267.2
Total		**44.7**	**121.3**	**226.6**	**1,153.6**

10.2.2.1(e) AN ESTIMATE OF THE EXTANT AREA AND OVERALL CONDITION OF THE POTENTIAL TEC REMAINING IN THE IBRA SUBREGION BEFORE AND AFTER THE IMPACT OF THE DEVELOPMENT HAS BEEN TAKEN INTO CONSIDERATION

The development will result in a loss of 2.8 per cent of the remaining area of CRCIF in the Cumberland subregion.

The extent and condition of CRCIF remaining in the subregion before and after the impact of the development is provided in Table 25-7. The largest percentage change relates to the TEC in thinned condition. Only very small changes occur to the TEC in intact condition (-1.9 per cent change).

Table 25-7: Extent and condition of Cooks River Castlereagh Ironbark Forest (PCT 725) before and after development

PCT	Condition	Current area in Cumberland subregion (ha)	Area in Cumberland subregion after the direct impacts of the development (ha)	Per cent loss of current area in Cumberland subregion (%)
725	Intact	836.6	820.6	-1.9
725	Thinned	187.1	168.4	-10.0
725	Scattered Trees	327.4	324.5	-0.9
Total		**1,351.1**	**1,313.5**	**-2.8**

10.2.2.1(f) AN ESTIMATE OF THE AREA OF THE POTENTIAL TEC THAT IS IN THE RESERVE SYSTEM WITHIN THE IBRA REGION AND THE IBRA SUBREGION

The area of CRCIF occurring within protected lands (land reserved under NPW Act) within the Cumberland subregion is 412.2 ha. This represents 30.5 per cent of the total area of the remaining TEC in the subregion.

The extent and condition of CRCIF within protected lands is provided in Table 25-8.

Table 25-8: Extent and condition of Cooks River Castlereagh Ironbark Forest (PCT 725) in protected lands

PCT	Condition	Area in protected lands within the Cumberland subregion (ha)
725	Intact	402.4
725	Thinned	5.8
725	Scattered Trees	4.0
	Total	**412.2**

10.2.2.1(g) THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION PROPOSAL'S IMPACT ON:

(i) ABIOTIC FACTORS CRITICAL TO THE LONG-TERM SURVIVAL OF THE POTENTIAL TEC

(ii) CHARACTERISTIC AND FUNCTIONALLY IMPORTANT SPECIES

(iii) THE QUALITY AND INTEGRITY OF AN OCCURRENCE OF THE POTENTIAL TEC THROUGH THREATS AND INDIRECT IMPACTS

The Final Determination (NSW Scientific Committee, 2011) and BioNet profile (OEH, 2019b) for CRCIF identify a range of threats to the TEC. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens, and dieback
- Invasive fauna

These threats and indirect impacts have the potential to degrade the condition of the TEC and reduce the long-term viability of the patches of the TEC, particularly in the following locations:

- Northern part of GPEC where the OSO corridor fragments TEC patches
- South-eastern part of WSA where urban development occurs immediately adjacent to several TEC patches

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. This includes a requirement to undertake mitigation in accordance with the *Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest* (DECC, 2008) within and adjacent to the TEC. Relevant actions under these commitments and specific mitigation measures for the TEC are discussed below for each identified indirect impact.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC by altering the mid and ground layers (NSW Scientific Committee, 2011). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

The diversity and composition of species will change with time since fire, and may also change in response to changes in fire frequency (NSW Scientific Committee, 2011). This is despite most plant species in the TEC being able to regenerate after fire from lignotubers and buds beneath the bark, as well as seeds stored in the soil (OEH, 2019b).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in the north of GPEC, and the south-east of WSA.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
    - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.
- A specific requirement in Appendix E of the Plan under Commitments 5 and 6 to apply best practice guidelines for managing the TEC (DECC, 2008). This includes specifics around fire management for the TEC.

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC

- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas
- The fire management requirements for the TEC specified in the best practice guidelines will be applied

WEED INVASION

The TEC is threatened with invasion and competition by weeds. It typically occurs on soils that are richer in nutrients compared to other soil types in the Sydney Basin bioregion, which means it is particularly susceptible to threats from weeds (DECC, 2008). The most serious threats are African Lovegrass, scramblers and vines, and urban weeds such as Mother of Millions (OEH, 2019b).

These weeds are already present within the nominated areas and pose a threat to the TEC. However, urban and transport development in the vicinity of the TEC has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds. The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development or transport corridors occur adjacent to the TEC and/or fragments patches of the TEC into smaller patches and introduces edge effects. Key risk areas include the northern part of GPEC and south-eastern part of WSA.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area (SCA). This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
    - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
    - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds
- A specific requirement in Appendix E of the Plan under Commitments 5 and 6 to apply best practice guidelines for managing the TEC (DECC, 2008). This includes specifics around weed management for the TEC.

Importantly for the TEC, weeds will be actively managed within the 110 ha to be added to conservation as part of the conservation program under the Plan.

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC

- There will be a range of planning controls to minimise the potential spread of weeds during and after construction
- The weed management requirements for the TEC specified in the best practice guidelines will be applied

INAPPROPRIATE HABITAT DISTURBANCE

Damage caused by human disturbance, such as motorbikes, bicycles, 4WD vehicles, rubbish dumping, trampling, and erosion is identified in the BioNet profile as a threat to the TEC (OEH, 2019b).

These activities have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the nominated areas may increase due to the urban development. Occurrences of the TEC considered most at risk are those in the northern part of GPEC and the south-eastern part of WSA.

The Plan incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including in the specific offset for the TEC – see below)
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

The main threat to the TEC is associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules. This can both encourage weed invasion and cause siltation and erosion (OEH, 2019b).

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are those in the northern part of GPEC and the south-eastern part of WSA.

The Plan incorporates a range of general measures to mitigate the risks associated with changes to hydrology. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement measures to manage hydrological impacts, including in relation to:
    - Water cycle management. For example:
        - Water management measures must comply with council's requirements for detention, drainage, and water sensitive urban design principles

        - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
    - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
    - Soil erosion and sedimentation. For example:
        - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
        - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures for major transport corridors based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines (NSW RTA and NGH Environmental Consultancy, 2011). These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed, and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

DISEASES, PATHOGENS AND DIEBACK

The TEC is potentially susceptible to dieback caused by the root-rot fungus *Phytophthora cinnamomi* (OEH, 2019b).

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of general measures to manage the risks associated with *Phytophthora cinnamomi*. In summary, these include:

- A commitment (Commitment 18) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
    - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
    - Entering into written agreements with delivery partners to implement priority disease control programs
- Incorporation of development controls into DCPs for each nominated area to require the preparation of Construction Environmental Management Plans that must set out measures to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora*

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species, including CRCIF (DECC, 2008). These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development

- Aggressive bird species which compete for resources including the introduced Indian Myna, and native species such as the Sulphur-crested Cockatoo

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the nominated areas and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers.

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 16) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCA. This includes a number of actions with the most relevant to the outcome for the species being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Incorporation of development controls into DCPs for each nominated area that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites

10.2.2.1(H) DIRECT OR INDIRECT FRAGMENTATION AND ISOLATION OF AN IMPORTANT AREA OF THE POTENTIAL TEC

Direct loss of CRCIF may cause fragmentation and isolation of remaining patches of the TEC, which may increase the susceptibility of the TEC to weed invasion and other edge effects and reduce its long-term viability.

Fragmentation and isolation of CRCIF will mainly occur in the following areas:

- In the northern part of GPEC within Wianamatta Regional Park associated with the OSO
- In the south-eastern part of WSA associated with urban development

The small area of scattered patches of the TEC in the central part of GPEC will be completed removed.

The most notable impact to CRCIF occurs within Wianamatta Regional Park. The patches of the TEC in this location form part of a larger, well-connected patch of native vegetation, and large parts of the patch are in intact condition. These impacts will lead to fragmentation of the TEC in this location, reducing the size and increasing the isolation of the areas that remain. This will increase the susceptibility of CRCIF in this location to weed invasion and other edge effects and reduce its long-term viability. The patch that is directly impacted is only marginally connected to the second occurrence of the TEC within Wianamatta Regional Park (to the east of Ropes Crossing) and as such, the development is not expected to increase the level of fragmentation to the TEC in this locality more broadly.

The patches of the TEC in the south-eastern part of WSA are already relatively fragmented and isolated as a result of existing industrial land use and farming. The urban development in this location is not considered to greatly increase the level of fragmentation and isolation in this location.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE POTENTIAL TEC IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of CRCIF in the Cumberland subregion. Several commitments are described in more detail the sections above.

Key commitments relevant to the TEC are:

- TEC-specific commitments or mitigation measures to:
  - Secure an offset target of 115 ha of CRCIF (Commitment 8.2) in conservation lands within the Cumberland subregion. This would increase the area of TEC protected within the Cumberland subregion from approximately 30 percent to approximately 39 per cent
  - Undertake management of fire, weeds and pest animals and disease control consistent with the *Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest* (DECC, 2008) (under Commitment 5 and 6)
- As part of securing a minimum of 5,325 ha of native vegetation in the SCA, undertake ecological restoration of priority areas secured for conservation within the Cumberland subregion (Commitment 13). This includes restoring up to 1,330 ha of native vegetation, including targeting CRCIF
- Manage weeds (Commitment 15) and pest animals (Commitment 16) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within SCAs. This includes preparing:
  - A Weed Control Strategy to guide and co-ordinate delivery of a weed control program
  - A Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
  - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
  - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.4 CUMBERLAND PLAIN WOODLAND

25.4.1 TEC BACKGROUND

Cumberland Plain Woodland in the Sydney Basin Bioregion (CPW) is a woodland or forest with an overstorey dominated by Grey Box (*Eucalyptus moluccana*) and Forest Red Gum (*E. tereticornis*), with Narrow-leaved Ironbark (*E. crebra*), Spotted Gum (*Corymbia maculata*) and Thin-leaved Stringybark (*E. eugenioides*) occurring less frequently. The TEC typically comprises an open tree canopy, a near-continuous groundcover dominated by grasses and herbs, sometimes with layers of shrubs and/or small trees (NSW Scientific Committee, 2009).

The TEC is listed under the EPBC Act as part of *Cumberland Plain Shale Woodlands and Shale Gravel Transition Forest in the Sydney Basin Bioregion* (DEWHA, 2009a).

CPW generally occurs on flat to undulating or hilly terrain up to about 350 m elevation but may also occur on locally steep sites and at slightly higher elevations, and on clay soils derived from Wianamatta Group geology, or more rarely alluvial substrates, on the Cumberland Plain (NSW Scientific Committee, 2009).

Several other TECs may intergrade with CPW, including CRCIF, *Shale Gravel Transition Forest in the Sydney Basin Bioregion (SGTF)* and *Moist Shale Woodland and Shale Sandstone Transition Forest* (SSTF) (NSW Scientific Committee, 2009).

CPW is restricted to the Sydney Basin Bioregion. It is known to occur in the Auburn, Bankstown, Baulkham Hills, Blacktown, Camden, Campbelltown, Fairfield, Hawkesbury, Holroyd, Liverpool, Parramatta, Penrith and Wollondilly LGAs (NSW Scientific Committee, 2009). The remaining area of the TEC is severely fragmented, with more than half of the remaining area occurring in patches of less than 80 ha in 2009 (NSW Scientific Committee, 2009).

25.4.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

CPW has been identified as a potential serious and irreversible impacts entity under the EES guidelines because it is currently in a rapid rate of decline (Principle 1 of the BC Regulation) and is subject to high levels of degradation or disruption of biotic processes (Principle 2 of the BC Regulation) (DPIE, 2020).

CPW is associated with the following PCTs:

- PCT 849 – Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain
- PCT 850 – Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain

The TEC has been mapped within the nominated areas and the Cumberland subregion on the basis of the extent and condition of these PCTs (see Chapter 11).

25.4.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of CPW in relation to the subject land is shown in Map 25-2.

CPW is relatively evenly distributed in scattered patches across the Cumberland subregion generally west of Parramatta and Liverpool, with the majority of large patches occurring in the centre and northern parts of the subregion.

The TEC has been mapped as occurring in all nominated areas.

25.4.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.2 of the BAM.

10.2.2.1(a) THE ACTION AND MEASURES TAKEN TO AVOID THE DIRECT AND INDIRECT IMPACT ON THE POTENTIAL ENTITY FOR AN SAII

Avoidance and minimisation of impacts to biodiversity values, including CPW, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The baseline mapping for this assessment has mapped 812.8 ha of CPW within the nominated areas (not including excluded lands). Approximately 303.8 ha (37.4 per cent) of this was avoided within the nominated areas as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 252.9 ha was avoided for biodiversity purposes
- 50.9 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-9.

The table shows that of the 147 ha of intact condition CPW (without excluded lands), the majority (109 ha or 74 per cent) has been avoided.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-9 shows the amounts of habitat within excluded lands for context only.

Table 25-9: Avoidance outcomes for Cumberland Plain Woodland (PCT 849 and 850)

Condition	Total area in nominated areas (ha)	Area in excluded lands (ha)	Area without excluded lands (ha)	Directly impacted (ha)	Avoided for biodiversity purposes (ha)	Avoided for other purposes (ha)	Total avoidance (ha)
Intact condition	613.5	524.0	89.4	31.5	47.6	10.4	57.9

Condition	Total area in nominated areas (ha)	Area in excluded lands (ha)	Area without excluded lands (ha)	Directly impacted (ha)	Avoided for biodiversity purposes (ha)	Avoided for other purposes (ha)	Total avoidance (ha)
Thinned condition	1,869.8	1,289.8	580.0	345.3	195.0	39.6	234.6
Scattered trees	335.0	191.6	143.4	132.2	10.3	0.9	11.2
DNG	539.9	99.9	440.1	422.5	17.0	0.5	17.5
Total	**3,358.2**	**2,105.3**	**1,252.8**	**931.5**	**269.9**	**51.4**	**321.3**

Avoidance of indirect impacts

Potential indirect impacts to CPW due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(b) THE AREA (HA) AND CONDITION OF THE TEC TO BE IMPACTED DIRECTLY AND INDIRECTLY BY THE DEVELOPMENT. THE CONDITION OF THE TEC IS TO BE REPRESENTED BY THE VEGETATION INTEGRITY SCORE FOR EACH VEGETATION ZONE

Direct impacts

A total of 931.5 ha of CPW will be directly impacted by the development. This is approximately 62.6% per cent of the TEC in the nominated areas (without excluded lands). The direct impacts of the development are mainly associated with urban development. The direct impacts mainly occur:

- Wilton: to most remaining patches of the TEC, including several large patches. These patches are mainly low condition (DNG or scattered trees) and occur primarily in the northern and central parts of the nominated area. Many of these patches are relatively isolated, although some occur adjacent to other native vegetation associated with the gorges and gullies along the edges of the nominated area
- GMAC: to many small to moderate sized scattered patches of mainly low to moderate condition (DNG, scattered trees or thinned) throughout the nominated area. Most of these patches are isolated, particularly in the northern section of the nominated area, although some occur adjacent to other native vegetation associated with the gorges and gullies along the edges of the southern part of the nominated area. Development will impact some intact patches in the southern part of the nominated area. These patches are generally small and narrow
- WSA: to several moderate to large patches of mainly low to moderate condition TEC (DNG, scattered trees or thinned) in two main areas – the southern arm of the nominated area, and the northern part of the nominated area near Luddenham Road, which will be impacted by the transport corridors (Outer Sydney Orbital (OSO)). Most patches are relatively isolated and surrounded by either farmland or existing urban development
- GPEC: to many scattered mostly small patches in moderate condition that are generally isolated from larger patches of native vegetation and surrounded by farmland or existing urban development. Two large areas of CPW occur in this nominated area around Jordan Springs west of Wianamatta Regional Park, and at Orchard Hills.

The direct impacts of the development on CPW are provided in Table 25-10.

Table 25-10: Direct impacts on Cumberland Plain Woodland (PCT 849 and 850)

PCT	Condition	Direct impacts (ha)						Vegetation integrity score
		Wilton*	GMAC*	WSA*	GPEC*	Transport#	Total	
849	Intact	1.6	10.7	6.1	0.1	9.0	**27.4**	53.9
849	Thinned	23.4	37.4	154.4	56.7	29.9	**301.7**	42.3
849	Scattered trees	23.8	26.3	57.1	3.3	10.1	**120.7**	18.3
849	DNG	148.7	28.2	38.8	8.9	2.8	**227.4**	24.1
850	Intact	0.0	4.0	0.0	0.0	0.0	**4.0**	58.1
850	Thinned	0.0	21.8	5.8	16.1	0.0	**43.6**	41.9
850	Scattered trees	0.9	6.9	1.6	2.2	0.0	**11.5**	38.1
850	DNG	159.6	12.3	0.2	23.0	0.0	**195.1**	25.7
Total		**357.9**	**147.7**	**263.9**	**110.2**	**51.7**	**931.5**	

* Impacts from urban development only within each nominated area
\# Impacts from transport corridors across all nominated areas

Indirect impacts

Potential indirect impacts to CPW due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(c) A DESCRIPTION OF THE EXTENT TO WHICH THE IMPACT EXCEEDS THE THRESHOLD FOR THE POTENTIAL ENTITY

No threshold has been established for CPW.

10.2.2.1(d) THE EXTENT AND OVERALL CONDITION OF THE POTENTIAL TEC WITHIN AN AREA OF 1,000 HA, AND THEN 10,000 HA, SURROUNDING THE URBAN CAPABLE LANDS

The extent and condition of CPW surrounding the urban capable lands are provided in Table 25-11. Due to the scale of the development, calculations were also presented based on a 1 km buffer and a 10 km buffer from the outer edge of the urban capable lands, as well as buffers of 1,000 ha or 10,000 ha as per the BAM.

Table 25-11: Extent and condition of Cumberland Plain Woodland (PCT 849 and 850) surrounding the urban capable lands

PCT	Condition	Area in 1,000 ha buffer	Area in 10,000 ha buffer	Area in 1,000 m buffer	Area in 10,000 m buffer
849	Intact	35.6	198.0	648.1	3,022.5
849	Thinned	357.1	703.0	1,221.9	3,253.7
849	Scattered trees	133.4	248.7	669.9	4,190.4
849	DNG	235.3	283.7	296.2	332.1
850	Intact	10.1	89.3	267.3	1,870.1
850	Thinned	53.3	138.4	251.5	1,010.9
850	Scattered trees	15.0	95.5	407.2	4,059.4
850	DNG	200.0	206.8	207.5	208.1
Total		**1,039.8**	**1,963.4**	**3,969.6**	**17,947.3**

10.2.2.1(E) AN ESTIMATE OF THE EXTANT AREA AND OVERALL CONDITION OF THE POTENTIAL TEC REMAINING IN THE IBRA SUBREGION BEFORE AND AFTER THE IMPACT OF THE DEVELOPMENT HAS BEEN TAKEN INTO CONSIDERATION

The development will result in a loss of 4.1 per cent of the remaining area of CPW in the Cumberland subregion.

The extent and condition of CPW remaining in the subregion before and after the impact of the development is provided in Table 25-12. The largest percentage changes relate to the TEC in very low condition (DNG). Only very small changes occur to the TEC in intact condition (-0.6 per cent change for PCT 849, and -0.2 per cent change for PCT 850).

Table 25-12: Extent and condition of Cumberland Plain Woodland (PCT 849 and 850) before and after the development

PCT	Condition	Current area in Cumberland subregion (ha)	Area in Cumberland subregion after the direct impacts of the development (ha)	Per cent loss of current area in Cumberland subregion (%)
849	Intact	4,292.6	4,265.1	-0.6
849	Thinned	3,552.5	3,250.8	-8.5
849	Scattered trees	5,940.8	5,820.1	-2.0
849	DNG	332.1	104.7	-68.5
850	Intact	2,657.3	2,653.3	-0.2
850	Thinned	1,117.2	1,073.5	-3.9
850	Scattered trees	4,895.2	4,883.7	-0.2
850	DNG	208.1	13.0	-93.8
Total		**22,995.7**	**22,064.2**	**-4.1**

Trend analysis for PCT 849

As part of the EPBC Act strategic assessment process for the nominated areas and transport corridors, a trend analysis looking at the extent and condition of PCT 849 over the life of the Plan was undertaken by RMIT University (Gordon and Peterson, 2019) (see Supporting Document D). The project (while only looking at one of the two PCTs that make up CPW) has direct relevance to the assessment of CPW as an SAII entity.

The trend analysis examined the potential impacts of development and offsetting under various scenarios on PCT 849 in the Cumberland subregion. It considered a summed score across the landscape for the PCT of extent and ecological condition (the latter being based on an approximation of the BAM vegetation integrity score).

The project involved two major components:

- A formal expert elicitation to gather quantitative knowledge regarding how the condition of PCT 849 will change over time under:
  - High or low intensity management
  - The case where the PCT is exposed to typical ongoing private land activities
- Quantitative modelling to simulate the urban development within the designated nominated areas and compensation via managing areas as biodiversity offsets in a strategically defined offset region and the ecological response of the PCT. The modelling included eight scenarios exploring different options for implementing biodiversity offsets which varied:
  - The timing of when offsets are implemented
  - The total area of offsets implemented
  - The type of management implemented for the offsets (low or high intensity)

The analysis found that:

- Existing landscape scale threats (e.g. weed invasion, grazing, rubbish dumping, disturbance from recreational activities) across the Cumberland subregion are significant and will result in an approximate 5.8% decline in the extent and condition of the PCT over the life of the Plan unless additional areas are managed
- The proposed impacts of development under the Plan will lead to approximately the same magnitude of losses (~ 5.8 %) to the PCT that will result due to existing landscape threats
- High intensity management and early offsetting will provide the greatest benefits to the outcomes of the PCT over the life of the Plan
- Securing approximately 1,600 ha of offsets for the PCT:
    - Will compensate for the impacts of development where earlier offsetting and higher intensity management is preferential by improving the extent and condition of the PCT over the life of the Plan
    - Has the potential to also contribute significantly to addressing the declines across the subregion due to existing landscape scale threats

Subsection (i) below sets out the actual offsets that are proposed under the Plan for CPW. These include a commitment to protect 2,803 ha of PCT 849 which is significantly greater than the modelled amount of 1,600 ha used in the trend analysis. The results of the trend analysis when considered in the context of the actual commitments of the Plan strongly indicate that PCT 849 will be substantially better off due to implementation of the Plan.

10.2.2.1(F) AN ESTIMATE OF THE AREA OF THE POTENTIAL TEC THAT IS IN THE RESERVE SYSTEM WITHIN THE IBRA REGION AND THE IBRA SUBREGION

The area of CPW occurring within protected lands (land reserved under NPW Act) within the Cumberland subregion is 1,289 ha. This represents 6 per cent of the total area of the remaining TEC in the subregion.

The extent and condition of CPW within protected lands is provided in Table 25-13.

Table 25-13: Extent and condition of Cumberland Plain Woodland (PCT 849 and 850) in protected lands

PCT	Condition	Area in protected lands within the Cumberland subregion (ha)
849	Intact	989.8
849	Thinned	323.3
849	Scattered trees	110.8
849	DNG*	N/A
850	Intact	152.1
850	Thinned	8.2
850	Scattered trees	25.3
850	DNG*	N/A
Total		**1,609.6**

* DNG mapping is not available outside of the nominated areas

10.2.2.1(G) THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION PROPOSAL'S IMPACT ON:

(I) ABIOTIC FACTORS CRITICAL TO THE LONG-TERM SURVIVAL OF THE POTENTIAL TEC

(II) CHARACTERISTIC AND FUNCTIONALLY IMPORTANT SPECIES THROUGH IMPACTS

(III) THE QUALITY AND INTEGRITY OF AN OCCURRENCE OF THE POTENTIAL TEC THROUGH THREATS AND INDIRECT IMPACTS

The Final Determination (NSW Scientific Committee, 2009) and BioNet profile (OEH, 2009) for CPW identify a range of threats to the TEC. Where these threats are present in the nominated areas and have the potential to be exacerbated

under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens, and dieback
- Invasive fauna

The greatest risk areas for these relevant threats are:

- Wilton: along the edges of the urban capable lands mainly around the outer edges of the nominated area, particularly in the northern part of the area
- GMAC: along the edges of the urban capable lands within the southern part of the nominated area
- WSA: along the edges of the urban capable lands
- GPEC: along the edges of the urban capable lands, in particular in the west and north of the nominated area

Impacts from inappropriate livestock grazing regimes was also identified in the Conservation Advice as a key threat. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate this risk across the nominated areas.

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for the TEC are discussed below for each identified indirect impact.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC (OEH, 2009). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Fire regimes influence the plant species composition and vegetation structure of the TEC and are also likely to influence other components of the community (NSW Scientific Committee, 2009). Fire intervals of 4 to 12 years are likely to maintain most understorey species within the TEC. Fire intervals which are too short are associated with reduced native plant diversity (NSW Scientific Committee, 2009). Disruption of ecological processes associated with altered fire regimes contributes to a very large reduction in the ecological function of the TEC (NSW Scientific Committee, 2009).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC, this includes areas in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton, where the TEC is much less extensive.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values

  - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
  - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
  - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

WEED INVASION

Weed invasion also poses a major threat to the TEC (NSW Scientific Committee, 2009). Weeds can displace native plants and reduce the diversity and regenerative capacity of the TEC. The Final Determination lists a wide range of weed species that threaten the TEC, including African Olive (O*lea europa* subsp. *cuspidata*), Bridal Creeper (*Asparagus asparagoides*) and a range of exotic grasses (NSW Scientific Committee, 2009).

These weeds are already present within the nominated areas and pose a threat to the TEC. However, urban development and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to the TEC and introduces edge effects. Key risk areas include in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
  - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction

  - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
  - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds

Importantly for the TEC, weeds will be actively managed within the offset to be secured for the TEC (see below).

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified as a threat to the TEC (OEH, 2009). This relates to a wide range of different mechanisms for disturbance including:

- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as cause weed invasion
- Inappropriate recreational activities such as 4WD and trail bike use which can directly impact areas of the TEC and facilitate processes such as erosion
- Removal of woody debris and firewood collection which changes the structure and habitat features of the TEC

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the nominated areas may increase due to the urban development. Occurrences of the TEC considered most at risk are those in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those location (including the offset to be secured for the TEC – see below)
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Development controls will be put in place to address potential impacts associated with construction

- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules (OEH, 2009). This can both encourage weed invasion and cause erosion and sedimentation.

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas include in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of general measures to mitigate the risks associated with changes to hydrology. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement measures to manage hydrological impacts, including in relation to:
    - Water cycle management. For example:
        - Water management measures must comply with council's requirements for detention, drainage, and water sensitive urban design principles
        - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
    - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
    - Soil erosion and sedimentation. For example:
        - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
        - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures for major transport corridors based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines (NSW RTA and NGH Environmental Consultancy, 2011). These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed, and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long-term viability. CPW at a Commonwealth level is recognised as being susceptible to dieback caused by the root-rot fungus *Phytophthora cinnamomi* (DoEE, 2018b).

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles, and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of general measures to manage the risks associated with *Phytophthora cinnamomi*. In summary, these include:

- A commitment (Commitment 18) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Incorporation of development controls into DCPs for each nominated area to require the preparation of Construction Environmental Management Plans that must set out the measures to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora*

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens, and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. Predation of native fauna by cats and foxes is specifically identified as a threat to the TEC (OEH, 2009). Pest animals can lead to declines in biodiversity through:

- Predation on native fauna
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the nominated areas and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and foxes are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats in the local area, which, in turn, may lead to an increase in feral cat numbers.

The Plan incorporates a range of measures to manage these risks. In summary, these include:

- A commitment (Commitment 16) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCA. This includes a number of actions with the most relevant to the outcome for the species being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Incorporation of development controls into DCPs for each nominated area that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites

10.2.2.1(H) DIRECT OR INDIRECT FRAGMENTATION AND ISOLATION OF AN IMPORTANT AREA OF THE POTENTIAL TEC

Direct loss of CPW may cause fragmentation and isolation of remaining patches of the TEC, which may increase the susceptibility of the TEC to weed invasion and other edge effects and reduce its long-term viability.

Fragmentation and isolation of patches of CPW will mainly occur in the following areas:

- Wilton: Development will remove most remaining patches of the TEC. Three larger patches of mostly moderate condition TEC will be reduced in size. These patches will not be isolated by the development and will remain contiguous with larger areas of native vegetation associated with the gorges and gullies on the edges of the nominated area, which will reduce the effects of fragmentation
- GMAC: Development will mostly remove scattered patches of mainly low to moderate condition TEC. Patches of the TEC that will remain are already generally isolated and surrounded by farmland or existing urban development, particularly in the southern part of the nominated area and the development will not generally result in further isolation of remaining patches. In some areas, remaining patches will remain contiguous with larger areas of native vegetation associated with the gorges and gullies on the edges and middle of the southern part of the nominated area, which will reduce the effects of fragmentation
- WSA: In the northern part of the nominated area near Luddenham Road, the OSO will fragment a large patch of mainly low to moderate condition TEC. In the southern part of the nominated area, an area of relatively well-connected patches of the TEC will be mostly removed and the TEC will only remain along a narrow riparian corridor. In both these cases, the development will reduce the size of the patch and increase the susceptibility of the TEC to weed invasion and other edge effects, which may reduce its long-term viability
- GPEC: In the northern part of the nominated area, a relatively narrow patch of the TEC that occurs within Wianamatta Regional Park will be fragmented by the OSO. This will reduce the size of the patch and increase the susceptibility of the TEC within the Regional Park to weed invasion and other edge effects. This is not expected to reduce the long-term viability of the TEC in this locality as the remaining patches will be managed for conservation in the Regional Park. In other parts of the nominated area, the development usually removes entire patches of the TEC and will not generally result in increased fragmentation or increased isolation of patches

10.2.2.1(i) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE POTENTIAL TEC IN THE IBRA SUBREGION

The Plan includes a range of commitments and actions that will contribute to the recovery of CPW in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments relevant to the TEC are:

- TEC-specific commitments to secure an offset target of 2,885 ha of CPW (Commitment 8.2) in conservation lands within the SCA. This includes a target of 2,150 ha of PCT 849 and a target of 735 ha of PCT 850. This would increase the area of TEC protected within the Cumberland subregion from approximately 6.9 percent to 19.5 percent.
- As part of securing a minimum of 5,325 ha of native vegetation in the SCA, undertake ecological restoration of priority areas secured for conservation within the Cumberland subregion (Commitment 13). This includes restoring up to 1,330 ha of native vegetation, including targeting CPW
- Manage weeds (Commitment 15) and pest animals (Commitment 16) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within the SCA. This includes preparing:
    - A Weed Control Strategy to guide and co-ordinate delivery of a weed control program
    - A Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

As outlined previously in subsection (e), the trend analysis (Gordon and Peterson, 2019) when considered in the context of the commitments of the Plan, strongly indicates that PCT 849 will be substantially better off due to implementation of the Plan under scenarios of high intensity management and early offsetting. While care needs to be taken in extrapolating the results of the analysis to PCT 850, it is considered highly likely that the commitments in the Plan will also provide substantial benefits to that PCT over the life of the Plan.

25.5 SHALE SANDSTONE TRANSITION FOREST

25.5.1 TEC BACKGROUND

Shale Sandstone Transition Forest in the Sydney Basin Bioregion (SSTF) is a forest or woodland with an overstorey that may include *Eucalyptus punctata*, *Eucalyptus resinifera*, one of the stringybarks (*Eucalyptus globoidea, Eucalyptus eugenioides, Eucalyptus sparsifolia, Eucalyptus agglomerata*). One or more ironbark species may be locally important. The understorey may be either grassy and herbaceous or shrubby with a notable amount of grass cover (although the presence of some shrubs, such as *Banksia* and *Persoonia* species, indicate the site may not be SSTF). In areas that have not been burnt for long periods the understorey may be dense. Species composition varies between sites depending on geographical location and local conditions (e.g. topography, relative influence of sandstone or shale) (NSW Scientific Committee, 1995).

The TEC is equivalent to the ecological community with the same name listed under the EPBC Act, although it is important to note that condition thresholds apply to the EPBC listed community (DoE, 2014a).

SSTF generally occurs on soils derived from a shallow shale or clay material overlying sandstone, or where shale-derived materials have washed down over sandstone-derived substrate. Such sites are generally close to the geological boundary between the Wianamatta Shale and the Hawkesbury Sandstone (NSW Scientific Committee, 1995). The contributing shale must come from the Wianamatta group. Shale lenses that occur in the Hawkesbury Sandstone provide a different chemistry and may relate to a different TEC (O'Hares Creek Shale Forest).

The TEC is confined to the Sydney Basin Bioregion and mostly restricted to areas transitional between clay soils derived from Wianamatta Shale and sandy soils derived from Hawkesbury Sandstone on the margins of the Cumberland Plain (NSW Scientific Committee, 1995). The main occurrences of the TEC are in the Hawkesbury, The Hills, Liverpool, Parramatta, Penrith, Campbelltown and Wollondilly LGAs (OEH, 2019k) and it extends west into the lower Blue Mountains. Many occurrences are linear s, which may be as narrow as 20 m wide (NSW Scientific Committee, 1995).

25.5.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

SSTF has been identified as a potential SAII entity under the OEH guidelines because it is it subject to high levels of degradation or disruption of biotic processes (Principle 2 of the BC Regulation) and a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (OEH, 2017g).

SSTF is associated with PCT 1395 – 'Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion'. The TEC has been mapped within the nominated areas and the Cumberland subregion on the basis of the extent and condition of this PCT (see Chapter 11)

25.5.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of SSTF in relation to the subject land is shown in Map 25-3.

The majority of SSTF within the Cumberland subregion occurs on the edges of the subregion outside the nominated areas north-west of Richmond, west of the Nepean River around Gulguer Nature Reserve, and in the southern part of the subregion around Tahmoor, Wilton, and Appin.

The TEC has been mapped as occurring in the following nominated areas:

- Wilton
- GMAC, mainly in the southern part of the nominated area
- A small area in far western GPEC

25.5.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.2 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID THE DIRECT AND INDIRECT IMPACT ON THE POTENTIAL ENTITY FOR AN SAII

Avoidance and minimisation of impacts to biodiversity values, including SSTF, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The baseline mapping for this assessment has mapped 2,640.2 ha of SSTF within the nominated areas (not including excluded lands). Approximately 2,180.5 ha (82.6 per cent) of this was avoided within the nominated areas as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,929.2 ha was avoided for biodiversity purposes
- 251.3 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-14.

The table shows that the majority of the total avoidance that has occurred (66.4 per cent) has been of SSTF in intact condition, and that of the 1,492.6 ha of intact condition SSTF (without excluded lands), the vast majority (1,446.8 ha or 96.9 per cent) has been avoided.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-14 shows the amounts of habitat within excluded lands for context only.

Table 25-14: Avoidance outcomes for Shale Sandstone Transition Forest (PCT 1395)

Condition	Total area in nominated areas (ha)	Area in excluded lands (ha)	Area without excluded lands (ha)	Directly impacted (ha)	Avoided for biodiversity purposes (ha)	Avoided for other purposes (ha)	Total avoidance (ha)
Intact condition	1,841.4	348.9	1,492.6	45.7	1,229.7	217.2	1,446.8
Thinned condition	986.8	270.8	716.0	145.6	538.1	32.3	570.5
Scattered trees	125.3	50.7	74.6	41.0	32.8	0.8	33.6
DNG	403.7	46.7	357.0	227.5	128.6	1.0	129.6
Total	**3,357.3**	**717.1**	**2,640.2**	**459.8**	**1,929.2**	**251.3**	**2,180.5**

Avoidance of indirect impacts

Potential indirect impacts to SSTF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(b) THE AREA (HA) AND CONDITION OF THE TEC TO BE IMPACTED DIRECTLY AND INDIRECTLY BY THE DEVELOPMENT. THE CONDITION OF THE TEC IS TO BE REPRESENTED BY THE VEGETATION INTEGRITY SCORE FOR EACH VEGETATION ZONE

Direct impacts

A total of 459.8 ha of SSTF will be directly impacted by the development. This is approximately 17.4 per cent of the TEC in the nominated areas (without excluded lands). The direct impacts of the development are mainly associated with urban development. The direct impacts mainly occur:

- Wilton: along the edges of the urban capable lands mainly around the outer edges of the nominated area, particularly in the northern part of the area
- GMAC: along the edges of the urban capable lands within the southern part of the nominated area

The direct impacts of the development on SSTF are provided in Table 25-15.

Table 25-15: Direct impacts on Shale Sandstone Transition Forest (PCT 1395)

PCT	Condition	Direct impacts (ha)						Vegetation integrity score
		Wilton*	GMAC*	WSA*	GPEC*	Transport#	Total	
1395	Intact	10.9	34.8	0.0	0.0	0.0	**45.7**	72.9
1395	Thinned	70.8	74.7	0.0	0.0	0.0	**145.6**	63.9
1395	Scattered trees	17.9	23.1	0.0	0.0	0.0	**41.0**	30
1395	DNG	171.2	56.3	0.0	0.0	0.0	**227.5**	28.4
Total		**270.9**	**188.9**	**0.0**	**0.0**	**0.0**	**459.8**	

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Indirect impacts

Potential indirect impacts to SSTF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(c) A description of the extent to which the impact exceeds the threshold for the potential entity that is specified in the Guidance to assist a decision-maker to determine a serious and irreversible impact

No threshold has been established for SSTF.

10.2.2.1(d) The extent and overall condition of the potential TEC within an area of 1000ha, and then 10,000ha, surrounding the urban capable lands

The extent and condition of SSTF surrounding the urban capable lands are provided in Table 25-16. Due to the scale of the development, calculations were also presented based on a 1 km buffer and a 10 km buffer from the outer edge of the urban capable lands, as well as buffers of 1,000 ha or 10,000 ha as per the BAM.

Table 25-16: Extent and condition of Shale Sandstone Transition Forest (PCT 1395) surrounding the urban capable lands

PCT	Condition	Area in 1,000 ha buffer	Area in 10,000 ha buffer	Area in 1,000 m buffer	Area in 10,000 m buffer
1395	Intact	85.8	1,178.0	2,409.1	5,410.8
1395	Thinned	198.6	674.5	963.6	1,657.0
1395	Scattered trees	45.5	103.7	439.6	2,676.4
1395	DNG	244.3	363.6	384.5	403.8
Total		**574.2**	**2,319.8**	**4,196.7**	**10,148.0**

10.2.2.1(e) An estimate of the extant area and overall condition of the potential TEC remaining in the IBRA subregion before and after the impact of the development has been taken into consideration

The development will result in a loss of 3.7 per cent of the remaining area of SSTF in the Cumberland subregion.

The extent and condition of SSTF remaining in the subregion before and after the impact of the development is provided in Table 25-17. The largest percentage change relates to the TEC in very low condition (DNG). Only very small changes occur to the TEC in intact condition (-0.7 per cent change).

Table 25-17: Extent and condition of Shale Sandstone Transition Forest (PCT 1395) before and after the development

PCT	Condition	Current area in Cumberland subregion (ha)	Area in Cumberland subregion after the direct impacts of the development (ha)	Per cent loss of current area in Cumberland subregion (%)
1395	Intact	6,404.7	6,358.9	-0.7
1395	Thinned	1,642.6	1,497.0	-8.9
1395	Scattered trees	4,085.3	4,044.3	-1.0
1395	DNG	402.1	174.7	-56.6
Total		**12,534.7**	**12,074.9**	**-3.7**

10.2.2.1(f) AN ESTIMATE OF THE AREA OF THE POTENTIAL TEC THAT IS IN THE RESERVE SYSTEM WITHIN THE IBRA REGION AND THE IBRA SUBREGION

The area of SSTF occurring within protected lands (land reserved under NPW Act) within the Cumberland subregion is 507.1 ha. This represents 4 per cent of the total area of the remaining TEC in the subregion.

The extent and condition of SSTF within protected lands is provided in Table 25-18.

Table 25-18: Extent and condition of Shale Sandstone Transition Forest (PCT 1395) in protected lands

PCT	Condition	Area in protected lands within the Cumberland subregion (ha)
1395	Intact	420.3
1395	Thinned	27.9
1395	Scattered trees	58.8
1395	DNG*	N/A
Total		**507.1**

* DNG mapping is not available outside of the nominated areas

10.2.2.1(g) THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION PROPOSAL'S IMPACT ON:

(i) ABIOTIC FACTORS CRITICAL TO THE LONG-TERM SURVIVAL OF THE POTENTIAL TEC

(ii) CHARACTERISTIC AND FUNCTIONALLY IMPORTANT SPECIES THROUGH IMPACTS

(iii) THE QUALITY AND INTEGRITY OF AN OCCURRENCE OF THE POTENTIAL TEC THROUGH THREATS AND INDIRECT IMPACTS

The Final Determination (NSW Scientific Committee, 1995) and BioNet profile (OEH, 2019k) for SSTF identify a range of threats to the TEC. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology

The greatest risk areas within Wilton and GMAC for these relevant threats are:

- Wilton: along the edges of the urban capable land mainly around the outer edges of the nominated area, particularly in the northern part of the area

- GMAC: along the edges of the urban capable land within the southern part of the nominated area

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for the TEC are discussed below for each identified indirect impact.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC (OEH, 2019k). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in and around Wilton and the southern part of GMAC where significant areas of the TEC are present.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
    - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas
- The measures in the Plan for Koalas in terms of protecting and managing habitat, and constraining access to bushland will help protect the TEC

WEED INVASION

The TEC is threatened with invasion of weeds. Weeds can displace native plants and reduce the diversity and regenerative capacity of the TEC. Weeds that are a particular threat are invasive exotic grasses like African love grass (*Eragrostis curvula*) and Chilean needle grass (*Nassella neesiana*), as well as Lantana (*Lantana camara*), Broad-leafed and Small-leaf Privet (*Ligustrum lucidum* and *L. Sinense*), African olive (*Olea europaea* subsp. *cuspidate*), and Bridal Creeper (*Myrsiphyllum asparagoides*), and environmental weeds such as Sweet Pittosporum (*Pittosporum undulatum*) (OEH, 2019k).

These weeds are already present within the nominated areas and pose a threat to the TEC. However, development within the nominated areas has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to the TEC and introduces edge effects. Key risk areas include:

- In north and north-west of Wilton, where the urban capable land impacts the edges of patches of the TEC connected to gorges and gullies on the edge of the nominated area
- In the southern part of GMAC, where the urban capable land impacts the edges of patches of the TEC connected to gorges and gullies on the edge and middle of the nominated area

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area (SCA). This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
    - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
    - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds

Importantly for the TEC, weeds will be actively managed within the offset to be secured for the TEC (see below).

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Final Determination and BioNet profile as a threat to the TEC. Disturbance can relate to a wide range of different mechanisms for disturbance including:

- Inappropriate mowing, slashing, or scrubbing of the understorey for reasons such as bushfire fuel reduction, grazing and perceived aesthetics
- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants
- Inappropriate recreational activities such as mountain bike use and 4WDs which can directly impact areas of the TEC and facilitate processes such as erosion

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance may increase due to development within the nominated areas. Occurrences of the TEC considered most at risk are those that occur in close proximity to development within Wilton and GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- A commitment (Commitment 7) to mitigate indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on Koalas. This is relevant to the TEC because large areas are identified as important Koala habitat. Of particular relevance to habitat disturbance are associated actions around the use of exclusion fencing which will assist in controlling access to Koala habitat. These measures will help minimise inappropriate habitat disturbance to the TEC within both Wilton and GMAC
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the offset to be secured for the TEC)
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- The measures in the Plan for Koalas in terms of protecting and managing habitat, and constraining access to bushland will help protect the TEC
- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules (OEH, 2019k). This can both encourage weed invasion and cause erosion.

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are:

- In north and north-west of Wilton
- In the southern part of GMAC

The Plan incorporates a range of general measures to mitigate the risks associated with changes to hydrology. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement measures to manage hydrological impacts, including in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage, and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures for major transport corridors based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines (NSW RTA and NGH Environmental Consultancy, 2011). These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed, and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

10.2.2.1(H) DIRECT OR INDIRECT FRAGMENTATION AND ISOLATION OF AN IMPORTANT AREA OF THE POTENTIAL TEC

Direct loss of SSTF may cause fragmentation and isolation of remaining patches of the TEC, which may increase the susceptibility of the TEC to weed invasion and other edge effects and reduce its long-term viability.

Fragmentation and isolation of patches of SSTF will mainly occur in the following areas:

- Wilton: along the edges of the urban capable lands mainly around the outer edges of the nominated area, particularly in the northern part of the area
- GMAC: along the edges of the urban capable lands within the southern part of the nominated area

Within both nominated areas, patches of the TEC are relatively well connected around the edges of the urban capable lands. In Wilton, this occurs mainly around the outer edges of the nominated area, particularly in the northern part. In GMAC, this occurs around the outer edges as well as through the middle of the southern part of the nominated area.

Urban development in these nominated areas mainly directly impacts the edges of the TEC and does not generally impact this connectivity. While direct impacts will reduce the size and width of some patches around the edges of the urban capable lands, it does not generally result in isolation of these patches.

Where direct impacts will impact connectivity between patches of the TEC, these areas are generally already only marginally connected as a result of existing urban development or farming, and as such, the development is not expected to increase the level of fragmentation to the TEC in the locality more broadly.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE POTENTIAL TEC IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of SSTF in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments relevant to the TEC are:

- TEC-specific commitments to secure an offset target of 1,455 ha of SSTF (Commitment 8.2) in conservation lands within the Cumberland subregion. This would increase the area of TEC protected within the Cumberland subregion from approximately 4 per cent to approximately 15.6 per cent
- As part of securing a minimum of 5,325 ha of native vegetation in the SCA, undertake ecological restoration of priority areas secured for conservation within the Cumberland subregion (Commitment 13). This includes restoring up to 1,330 ha of native vegetation, including targeting SSTF
- Manage weeds (Commitment 15) and pest animals (Commitment 16) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within SCAs. This includes preparing:
    - A Weed Control Strategy to guide and co-ordinate delivery of a weed control program
    - A Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.6 ALLOCASUARINA GLAREICOLA

25.6.1 SPECIES BACKGROUND

Allocasuarina glareicola is an erect, smooth-barked shrub with cones that grows to approximately 2 m tall (DoEE, 2018a; OEH, 2018a). The species is monoecious or dioecious and flowers around October each year. The time taken for the plants to flower and set seed is not known. Regeneration is commonly by suckers. Root suckers can appear up to 3 m from the parent plant, where clumps of hundreds of stems may be a single individual. Seedling recruitment has only been observed at one site. The species is wind pollinated which means the distance between individuals may be a critical factor in enabling pollination and seed set (DoEE, 2018a; OEH, 2018a).

A. glareicola inhabits Castlereagh woodland and open woodland (with *Eucalyptus parramattensis, Eucalyptus fibrosa, Angophora bakeri, Eucalyptus sclerophylla and Melaleuca decora*). It occurs on strongly acidic soils with low fertility (DoEE, 2018a; OEH, 2018a).

Records are primarily restricted to the Castlereagh and Londonderry areas of the Cumberland Plain where there are 36 known occurrences of the species, with an outlier population found in Liverpool (Holsworthy Military Area). The total range of the species is approximately 36 km^2.

25.6.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

A. glareicola is being assessed as a candidate species credit species for GPEC. The species has been also identified as a potential SAII entity under the DPIE guidelines (Principle 3 of the BC Regulation) (DPIE, 2019), as it has a very highly restricted geographic distribution.

25.6.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of *A. glareicola* in relation to the subject land is shown in Map 25-4.

GPEC occurs within the southern extent of *A. glareicola's* stronghold in the Castlereagh and Londonderry areas.

There is one known population of *A. glareicola* within the nominated areas. This occurs in GPEC, located within a rail corridor along Hobart St in St Marys. This population is disjunct from the majority of known records which occur approximately 8 km to the north and are generally associated with larger, more intact remnants of native vegetation. The population in St Marys is located approximately 1.2 km from the nearest urban capable land.

Approximately 200 ha of potential habitat for the species has been identified in the nominated areas. This occurs in GPEC. The majority of potential habitat occurs within the Wianamatta Regional Park in the northern part of GPEC. A smaller patch of potential habitat has been mapped in Orchard Hills towards the middle of GPEC. The remaining habitat areas exist as scattered and isolated remnants across the eastern half of GPEC.

25.6.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including *A. glareicola*, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The population of *A. glareicola* within GPEC occurs outside the urban capable land and has been avoided.

The baseline mapping for this assessment has mapped 32.3 ha of potential habitat for *A. glareicola* within GPEC (not including excluded lands). Approximately 14.8 ha (46.1 per cent) of this was avoided within GPEC as part of the design of the urban capable land and transport corridors (not including excluded lands). All of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 25-19.

Table 25-19: Avoidance outcomes for *A. glareicola*

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	200	167.7	32.3	17.4	14.8	0.1	14.9

Avoidance of indirect impacts

Potential indirect impacts to *A. glareicola* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within the nominated areas will not directly impact on any records or known populations of *A. glareicola.*

Potential indirect impacts to *A. glareicola* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

No threshold has been established for *A. glareicola.*

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 17.4 ha of potential habitat will be directly impacted by the development. This is 53.9 per cent of the potential habitat in the nominated areas (not including excluded lands). The direct impacts of the development are associated with urban development and a transport corridor (the M7/Ropes Crossing Link Road). The main direct impacts occur:

- Along the northern boundary of GPEC within the alignment of the M7/Ropes Crossing Link Road
- Two scattered patches of potential habitat at Orchard Hills, which will be impacted by urban development

Although survey confirmed the species is absent from the OSO, the OSO alignment does bisect two areas of mapped potential habitat to the east of west of the OSO alignment.

The direct impacts of the development on *A. glareicola* are provided in Table 25-20.

Table 25-20: Direct impacts on *A. glareicola*

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	0	0	0	12.9	4.5	17.4

Impacts to habitat within northern GPEC

The M7/Ropes Crossing Link Road impacts on 4.4 ha of potential habitat along the northern boundary of GPEC. The habitat impacted is contiguous with mapped habitat in Shanes Park.

Although not directly impacting on mapped habitat, the OSO corridor will lead to fragmentation of potential habitat within Wianamatta Regional Park, leading to a number of smaller, isolated patches of vegetation. This fragmentation may increase impacts associated with edge effects (primarily weeds) and this has the potential to compromise the suitability of remaining habitat areas directly adjacent to development.

The species was confirmed absent within the OSO corridor during project surveys, and the likelihood that the species actually occurs within lands adjacent to the corridor is considered low given:

- The area forms part of a Regional Park which is managed by the NSW NPWS and would be well traversed
- The species is a conspicuous shrub which can be surveyed for throughout the year

This low likelihood of occurrence considerably reduces the risk of impacts to *A. glareicola* on key life-cycle processes. Furthermore, the species primarily regenerates through suckers and occasionally via wind pollination and neither of these processes are likely to be affected by fragmentation of potential habitat in this location.

Impacts to habitat at Orchard Hills

The loss of potential habitat for *A. glareicola* at Orchard Hills is associated with small remnants of scattered vegetation surrounded by houses and farmland. The extent of cleared land in the area means that impacts are unlikely to increase edge effects to retained habitat areas or further reduce their viability.

A section of potential habitat within the urban capable land which could be accessed as part of this biodiversity certification process was surveyed and the species was not observed. It is generally considered unlikely that potential habitat in this area contributes to the ongoing survival or viability of the species more broadly.

Indirect impacts

Potential indirect impacts to *A. glareicola* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(e) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat areas within GPEC is unlikely to affect the ecology of *A. glareicola* in the locality because:

- There is a low likelihood the species occurs within this habitat
- The loss and extent of fragmentation of potential habitat will not affect the key life-cycle processes of the species, which primarily regenerates through suckers and occasional seed production via wind pollination

10.2.3.1(f) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat areas within GPEC is unlikely to fragment or isolate any local populations of *A. glareicola.* There will be fragmentation of potential habitat from impacts caused by the M7/Ropes Crossing Link Road. Further fragmentation may occur within Wianamatta Regional Park as a result of the

OSO corridor bisecting two areas of potential habitat. However, this is considered to have limited implications for the species in the region given the low likelihood of occurrence within this habitat.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Potential habitat within GPEC occurs within the southern extent of the *A. glareicola* stronghold in the Castlereagh and Londonderry areas, and is within the geographic extent of the species.

There is one known population within the nominated area in St Marys. This population is disjunct from the majority of known records which occur approximately 8 km to the north and are generally associated with larger, more intact remnants of native vegetation and will not be directly or indirectly impacted by development.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile and additional available information for *A. glareicola* identify a range of threats to the species (DoEE, 2018a; OEH, 2018a). Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Habitat degradation from rubbish dumping and unrestricted access
- Weed invasion
- Inappropriate fire regimes

The greatest risk areas within GPEC for these relevant threats are:

- The southern end of Shanes Park where M7/Ropes Crossing Link Road occurs adjacent to potential habitat areas
- The north-eastern section of Wianamatta Regional Park, where the OSO corridor bisects two areas of potential habitat

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for *A. glareicola* are discussed below for each identified indirect impact.

HABITAT DEGRADATION

Habitat degradation through unrestricted public access and rubbish dumping have been identified as a key threat to *A. glareicola* (OEH, 2018a). Development within GPEC may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

The Plan incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand

and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

WEED INVASION

A. glareicola is threatened with invasion and competition by weeds, with African lovegrass *(Eragrostis curvula)*, Whisky grass (*Andropogon virginicus*), *Pennisetum clandestinum*, *Ricinus communis* and Asparagus fern considered to be the main competitors (OEH, 2018a). These weeds are already present within the Strategic Assessment Area. However, urban and transport development within GPEC has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *A. glareicola*:
    - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
    - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds

INAPPROPRIATE FIRE REGIMES

A. glareicola can regenerate following fire. However, plants may be damaged and fruit production and seed set prevented by too frequent fires (OEH, 2018a). Increased human activity within GPEC increases the risk of fire to habitat areas supporting the species.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for *A. glareicola* being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans

- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
    - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *A. glareicola*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 1,159.6 ha of potential habitat mapped within protected areas. This includes potential habitat within:

- Wianamatta Regional Park
- Wianamatta Nature Reserve
- Castlereagh Nature Reserve
- Agnes Banks Nature Reserve
- Windsor Downs Nature Reserve

Eleven records (likely to comprise a single biological population) occur within the Castlereagh Nature Reserve. No other occurrences of the species are currently protected.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of *A. glareicola* in the Cumberland subregion. Several commitments are described in more detail the sections above.

Key commitments relevant to the species are:

- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for *A. glareicola* in the SCA, as there is approximately 453.7 ha of mapped potential habitat in the SCA for this species
- Manage weeds (Commitment 15) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within the SCA. This includes preparing a Weed Control Strategy to guide and co-ordinate delivery of a weed control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.7 CHALINOLOBUS DWYERI

25.7.1 SPECIES BACKGROUND

Large-eared Pied Bat (*Chalinolobus dwyeri*) is a small to medium insectivorous bat with shiny, black fur (DERM, 2011).

The species appears to roost predominantly in caves and crevices in sandstone cliffs and forage in nearby high-fertility forest or woodland near watercourses and in gullies (DERM, 2011). Roosting areas can also include old mines and disused mud nests. The species is generally constrained to 'areas within two kilometres of rocky areas containing caves, overhangs, escarpments, outcrops, or crevices, or within two kilometres of old mines or tunnels' (OEH, 2019a).

Large-eared Pied Bat has specific requirements in relation to the structure of breeding roosts. Caves need to be high and deep enough to allow juvenile bats to learn to fly and have indentations in the roof to allow the capture of heat. These physical characteristics are very uncommon in the landscape (DERM, 2011). The species is not known to roost in tree hollows (DERM, 2011). The species breeds in early winter and young are born in early summer. The species uses the same maternity roosting sites over many years (DERM, 2011).

Almost all records of the Large-eared Pied Bat are within several kilometres of cliff lines or rocky terrain. Evidence suggests the species does not usually forage in sandstone habitat and prefers fertile valleys and plains, as well as areas with moderately-tall to taller trees along waterways (DERM, 2011).

Habitat critical to the survival of the species comprises:

- Breeding sites
- Sandstone cliffs and fertile wooded valley habitat within close proximity of each other (DERM, 2011)

Large-eared Pied Bat occurs from Shoalwater Bay in central Queensland to Ulladulla in south-eastern NSW. In NSW, the species is generally rare with a very patchy distribution. It is found in the north east at Coolah Tops, Mt Kaputar and Warrumbungle National Park and in sandstone areas of the Sydney Basin and the western slopes and plains including Pilliga Nature Reserve (DERM, 2011). The area of occupancy is estimated to be 9,120 km^2 (DoEE, 2018a).

The species is known to breed in very few locations across NSW and the distance bats move from the maternity roost to over-wintering roosts has not been established, but is likely to be less than 100 km (DoEE, 2018a). As such all records within the Cumberland subregion are considered likely to be from the same breeding population.

Records for the Large-eared Pied Bat are widespread surrounding the Cumberland subregion and some records occur within the subregion. Records occur within Wilton and GMAC and adjacent to GPEC.

25.7.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

The Large-eared Pied Bat is being assessed as a candidate Species Credit Species for Wilton, WSA and GMAC.

The species has been identified as a potential SAII entity under the TBDC because it has a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (DPIE, 2020). The species is also likely to be a potential entity because of Principle 4 of the BC Regulation as breeding habitat is likely to be irreplaceable.

The species has been identified as a potential SAII entity in relation to potential breeding habitat and the presence of breeding individuals. Potential breeding habitat comprises:

> *PCTs associated with the species within 100 m of rocky areas containing caves, or overhangs or crevices, cliffs or escarpments, or old mines, tunnels, culverts, derelict concrete buildings*

For the purposes of this BCAR, potential breeding habitat was mapped on the basis of:

- Associated PCTs as defined in TBDC in 'intact', 'thinned' and 'scattered trees' condition, and that are:
  - Within areas of Hawkesbury Sandstone and Minchinbury Sandstone geology, and
  - Within 200 m of locations where caves, crevices and cliffs are more likely to occur

Locations where caves, crevices and cliffs are more likely to occur were mapped by:

- Manipulation of a bare earth Digital Elevation Model to produce a layer that showed the mean elevation within a 30 m x 30 m grid surrounding each 1 m elevation grid cell
- Creation of a Topographic Position Index to identify the height of each 1 m cell above/below local mean elevation
- Reclassification of the Topographic Position Index to identify only areas that were high enough above the local mean elevation to create a topographic brake that might support cliffs
- Overlay the cliffs layer with a sandstone geology layer to exclude areas outside sandstone geology

The cliffs layer was validated through inspection of aerial photos and knowledge of the topography and landscape of the nominated areas, as well as site observations during surveys.

The potential breeding habitat was not able to be confirmed as actual breeding habitat. While Anabat surveys were undertaken for the species within a part of the northern section of Wilton, the surveys did not confirm the presence of breeding habitat or breeding individuals. The species was not detected during surveys.

25.7.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of Large-eared Pied Bat in relation to the subject land is shown in Map 25-5.

Records for the Large-eared Pied Bat are widespread surrounding the Cumberland subregion and some records occur within the subregion. A population of Large-eared Pied Bat occurs within Wilton and the southern part of GMAC associated with several records. Within Wilton, a cluster of recent records (as recent as 2016) occur in the vicinity of existing development in the central-eastern section of the nominated area. Within GMAC, a few recent records (as recent as 2014) occur in the Gilead area around the centre of the southern section of the nominated area.

Interrogation of the observation codes of records for the species indicate there are no known roost or breeding sites for the species within the nominated areas (OEH, 2019a).

Approximately 1,093.9 ha of potential breeding habitat for the Large-eared Pied Bat has been identified in the nominated areas. This occurs within Wilton and the southern section of GMAC.

25.7.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(a) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including Large-eared Pied Bat, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

Records associated with a population of Large-eared Pied Bat have been avoided within the nominated areas, although one record in GMAC occurs on the very edge of the urban capable land.

The baseline mapping for this assessment has mapped 882.2 ha of potential breeding habitat for Large-eared Pied Bat within Wilton and GPEC (not including excluded lands). Approximately 876.5 ha (99.3 per cent) of this was avoided as part of the design of the urban capable land and transport corridors (not including excluded lands). Of this:

- 452 ha was avoided for biodiversity purposes
- 424.5 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-21.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-21 shows the amounts of habitat within excluded lands for context only.

Table 25-21: Avoidance outcomes for Large-eared Pied Bat

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	1,093.9	211.6	882.2	5.8	452	424.5	876.5

Avoidance of indirect impacts

Potential indirect impacts to Large-eared Pied Bat due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(b) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development in the nominated areas will not directly impact on records or known populations of Large-eared Pied Bat.

Potential indirect impacts to Large-eared Pied Bat potential breeding habitat due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(c) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

Breeding habitat has been identified as an impact threshold for Large-eared Pied Bat.

While Anabat surveys were undertaken for the species within a part of the northern section of Wilton, the surveys did not confirm the presence of breeding habitat or breeding individuals.

10.2.3.1(d) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 7.5 ha of potential breeding habitat will be directly impacted by the development. This is 0.8 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development. The main direct impacts occur at the edges of Wilton and the southern part of GMAC.

The direct impacts of the development on Large-eared Pied Bat are provided in Table 25-22.

Table 25-22: Direct impacts on Large-eared Pied Bat

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential breeding habitat (ha)	3.6	2.2	0	0	0	5.8

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

The impacts to potential breeding habitat within Wilton and GMAC are unlikely to affect life cycle processes or impact the viability of any local population of Large-eared Pied Bat because:

- While roosting or breeding sites may occur, there are no known roosting or breeding sites for the species in the area
- Only a very small proportion of potential breeding habitat is directly impacted. The vast majority of potential breeding habitat has been avoided for biodiversity or other purposes
- The impacts are unlikely to cause fragmentation or isolation of potential breeding habitat because only the fringes of potential breeding habitat that occurs on the edges of gorges and gullies are impacted
- The corridors of potential breeding habitat that exist along the gorges and gullies are maintained
- Potential breeding habitat in the nominated areas forms a relatively small part of much broader and intact areas of habitat to the north and west of the Plan Area and to the south of Sydney

10.2.3.1(e) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential breeding habitat within the Wilton and GMAC is unlikely to affect the ecology of any local population of Large-eared Pied Bat in the area, including because:

- Only a very small proportion of potential breeding habitat is directly impacted

- The impacts are unlikely to cause fragmentation or isolation of potential breeding habitat and the corridors of potential breeding habitat that exist along the gorges and gullies are maintained

10.2.3.1(f) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential breeding habitat within Wilton and GMAC is unlikely to cause fragmentation or isolation of habitat because only the edges of potential breeding habitat are impacted and the corridors of habitat that exist along the gorges and gullies are maintained.

10.2.3.1(g) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

All records within the Cumberland subregion are considered likely to be from the same breeding population.

While roosting or breeding sites may occur, development within Wilton and GMAC will not directly impact any known roosting or breeding sites for Large-eared Pied Bat and will only impact a very small proportion of potential breeding habitat for the species in the nominated areas around the edges of this habitat.

The development is therefore not considered likely to affect the broader population in the Cumberland subregion.

Potential breeding habitat within Wilton and GMAC is not at the limit of the species range. Records for the species are widespread surrounding the Cumberland subregion.

10.2.3.1(h) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile (OEH, 2017h) and Recovery Plan (DERM, 2011) for the Large-eared Pied Bat identify a range of threats to the species Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Use of pesticides
- Disturbance of roosts from human recreational activities
- Fire in the proximity of roosts
- Predation by introduced predators

The greatest risk areas within Wilton and GMAC for these relevant threats are around the edges of the nominated areas along gorges and gullies associated with waterways, including the Nepean River.

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for the Large-eared Pied Bat are discussed below for each identified indirect impact.

USE OF PESTICIDES

Use of pesticides has been identified as a threat to the Large-eared Pied Bat. Poisoning of pest animals may occur during implementation of the Plan as part of the Pest Animal Control Implementation Strategy (Commitment 16).

The Plan includes Action 3 under Commitment 16, as follows: "*Ensure that the Pest Animal Control Implementation Strategy specifies the use of pest control techniques that will reduce the risk of secondary poisoning from Pindone or second-generation rodenticides*"

This measure is considered to be sufficient to address the threat posed to the Large-eared Pied Bat.

DISTURBANCE OF ROOSTS FROM HUMAN RECREATIONAL ACTIVITIES

Disturbance of roosts from recreational activities such as bushwalking, caving and abseiling is identified as a threat to the Large-eared Pied Bat. Regular disturbance can lead to bats abandoning roosts or depleting essential fat reserves (DERM, 2011).

Areas considered most at risk from increased disturbance due to recreational activities are those that occur in close proximity to development within Wilton and GMAC. Roosting and maternity caves are most likely to be located within the sandstone areas adjacent to and surrounding the Strategic Assessment Area. Much of this land is protected for conservation or as part of Sydney's drinking water catchment and should have existing management frameworks to prevent inappropriate access and use.

The Plan incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- A commitment (Commitment 7) to mitigate indirect impacts from urban, infrastructure and major infrastructure (transport) development on Koalas. This is relevant to the species because a lot of the mapped habitat for the Large-eared Pied Bat is identified as important Koala habitat. Of particular relevance to habitat disturbance are associated actions around the use of exclusion fencing which will assist in controlling access to Koala habitat. These measures will help minimise inappropriate habitat disturbance to potential habitat within both Wilton and GMAC
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations. It is noted that 2,413.1 ha of potential habitat for the Large-eared Pied Bat is contained within the three conservation reserves proposed by the Plan
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan, combined with existing management of protected areas adjacent to the Plan Area is expected to adequately manage the risk to the species from inappropriate recreational use.

FIRE IN THE PROXIMITY OF ROOSTS

Bushfires and prescribed burning are identified as a key threat to the Large-eared Pied Bat as they are potentially susceptible to direct mortality from heat and smoke if the fire is close to their relatively shallow cave roosts (DERM, 2011). Changes in foraging resources and prey species as a result of altered fire regimes may also impact the species (DERM, 2011).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for the Large-eared Pied Bat being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk

- Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the Large-eared Pied Bat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

PREDATION BY INTRODUCED PREDATORS

Predation by introduced predators such as cats, foxes and rats has been identified in the Recovery Plan as a possible, but unknown, threat to the Large-eared Pied Bat. Concerns relate to predation on individuals where they are forced to roost close to the ground (DERM, 2011).

Existing land use within the nominated areas and surrounding region includes residential areas and farming, which means cats are unlikely to pose a novel threat to the species in the area. However, the extent of proposed new urban development under the Plan means the threat is likely to be exacerbated.

Appendix E of the Plan contains the following measure: "Where permitted and appropriate, contain domestic cats and dogs in new residential areas during operation of the development at the urban/bushland interface consistent with relevant Council guidelines." This measure will be implemented via the Mitigation Measures Guideline and DCP template and applies in Wilton and GMAC. Although this measure does not specifically identify the Large-eared Pied Bat as a target species, it nonetheless is likely to benefit the species through mitigating the threat of increased densities of domestic cats.

The Plan incorporates a range of measures to manage the risks associated with introduced predators. In summary, these include:

- A commitment (Commitment 16) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Incorporation of development controls into DCPs for each nominated area that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites

These measures are considered to adequately mitigate the threat to the species.

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 25 ha of potential breeding habitat for the Large-eared Pied Bat mapped within protected areas in the nominated areas. The number of known breeding sites in NSW is very limited. However, other protected areas in NSW where the species is known to occur include (DERM, 2011):

- Bouddi National Park
- Big Scrub Flora Reserve
- Blue Mountains National Park
- Bungonia Nature Reserve
- Coolah Tops National Park
- Goulburn River National Park
- Mt Kaputar National Park
- Morton National Park
- Munghorn Gap Nature Reserve
- Pilliga Scrub Nature Reserve
- Richmond Range National Park
- Royal National Park
- Warrumbungle National Park
- Wollemi National Park
- Yengo National Park

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of Large-eared Pied Bat in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments relevant to the species are:

- Manage pest animals in strategic locations in the Cumberland subregion (Commitment 16) to reduce threats to conservation lands secured within the SCA. This includes preparing a Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

Due to the low risk of direct impacts on Large-eared Pied Bat potential breeding habitat, the Plan does not include any specific commitment to secure any known or potential breeding habitat in conservation lands.

However, the Plan includes a commitment (Commitment 8) to secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA. Given that several records of Large-eared Pied Bat occur within and immediately adjacent to the SCA, some of this land is likely to contain potential breeding habitat for this species.

25.8 HIBBERTIA FUMANA

25.8.1 SPECIES BACKGROUND

Hibbertia fumana is a small low shrub or sub-shrub (OEH, 2020).

Little is known about the life history and ecology of the species. Regeneration can occur through suckers, suggesting it may be able to resprout from rootstock following fire (TSSC, 2016b). Peak flowering times are spring to early summer, although the species appears to be capable of minor sporadic flowering at other times of the year as a response to suitable climatic conditions (Miller, 2018b).

H. fumana inhabits areas of woodland generally with an open understorey. Within the nominated areas, the species is associated with the following PCTs and transition zones between these (Miller, 2018a):

- PCT 724 - Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain
- PCT 725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain
- PCT 808 – Derived shrubland on Tertiary Gravels of the Cumberland Plain
- PCT 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain
- PCT 1067 - Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain

The species has a highly restricted range and until very recently was only known from only two populations:

- Moorebank (population size of approximately 370 individuals)
- Bankstown Airport (population size unknown) (Miller, 2018b)

However, it appears that as a result of recent surveys "populations of this species have been detected over a wider range within greater Sydney stretching from Richmond to Mittagong" (OEH, 2020). These records are not available to inform the assessment at this stage.

At Moorebank, the population mainly occurs within a transition zone between Castlereagh Scribbly Gum Woodland and Castlereagh Ironbark Forest, and in soils of fine sandy clay loam. It has the potential to occur in similar intergrade alluvial habitats rich in sands and laterite in other parts of Western Sydney (OEH, 2020).

The population at Moorebank is surrounded by existing development, including urban development, particularly to the north, east and west of the site. A rail line occurs along the boundary of southern end of the site. Habitat at the site is disturbed, and the population is traversed by a disused railway line. Proposed infrastructure in the area will result in further habitat loss and disturbance (TSSC, 2016b). Habitat at the site at Bankstown Airport is heavily disturbed – the site is managed and is routinely slashed to a height of about 10 cm (Miller, 2018b).

It should be noted that *H. fumana* is difficult to survey and may have been overlooked in past surveys as it:

- Has only recently been described
- Is extremely cryptic
- Is easily misidentified and/or overlooked as a depauperate version of other species

25.8.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

Hibbertia fumana is being assessed as a candidate species credit species in all four nominated areas.

The species has been identified as a potential SAII entity under the EES guidelines because it has a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (OEH, 2017g).

Two expert reports have been prepared for *H. fumana* by Cumberland Flora & Fauna Interpretive Services. One for GPEC and WSA (Miller, 2018a) and one for Wilton and GMAC (Miller, 2018b).

25.8.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of *H. fumana* in relation to the subject land is shown in Map 25-6.

There are no records of *H. fumana* in the nominated areas.

Targeted surveys for the species were undertaken as part of the expert report for *H. fumana* within some areas of habitat similar to the sites that support the populations of the species. Areas targeted for survey are shown in the expert report (see Supporting Document C). Targeted surveys were also undertaken in small areas of the nominated areas by ecological consultants as part of the biodiversity certification process. The species was not recorded during any of these surveys.

The two known populations of *H. fumana* occur outside the nominated areas. The population at Moorebank occurs 1.2 km to the north-east of GMAC, and the population at Bankstown Airport occurs about 9 km from GMAC.

Approximately 1,716.4 ha of potential habitat for *H. fumana* has been identified within the nominated areas.

25.8.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(a) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including *H. fumana*, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The only known populations of *H. fumana* occur outside the nominated areas. Avoidance of impacts to these populations were therefore not a relevant consideration.

The baseline mapping for this assessment has mapped 1,299 ha of potential habitat for *H. fumana* within the nominated areas (not including excluded lands). Approximately 1,225.3 ha (94.3 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,083.7 ha was avoided for biodiversity purposes
- 141.6 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-23.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-23 shows the amounts of habitat within excluded lands for context only.

Table 25-23: Avoidance outcomes for *H. fumana*

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	1,716.4	417.3	1,299	73.8	1,083.7	141.6	1,225.3

Avoidance of indirect impacts

Potential indirect impacts to *H. fumana* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(b) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within the nominated areas will not directly impact on any records or known populations of *H. fumana*.

Potential indirect impacts to *H. fumana* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(c) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for *H. fumana*.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 73.8 ha of potential habitat will be directly impacted by the development. This is 5.7 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development. The direct impacts mainly occur:

- WSA: habitat mapped in the south-east corner of WSA
- GMAC: within the areas mapped as 'likely habitat' by the expert in the south-west corner of GMAC (see Supporting Document C)
- Wilton: along the edges of the urban capable land in the northern part of the nominated area

Surveys confirmed *H. fumana* as absent within the OSO corridor, however mapped potential habitat remains present within the Wianamatta Regional Park in the northern part of GPEC. The OSO alignment bisects two areas of 'low probability' habitat for the species.

The direct impacts of the development on *H. fumana* are provided in Table 25-24.

Table 25-24: Direct impacts on *H. fumana*

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	28.3	7.1	6.9	0	31.5	73.8

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Impacts to potential habitat within GPEC

Surveys for the species confirmed that the species was not present within the OSO alignment, however the OSO does bisect potential habitat for *H. fumana* within the north-eastern part of Wianamatta Regional Park. This will lead to loss and fragmentation of potential habitat at this location, leading to a number of smaller, isolated patches of habitat. This fragmentation may increase impacts associated with edge effects and weed invasion and this has the potential to compromise the suitability of remaining habitat areas directly adjacent to the development.

Surveys for *H. fumana* were undertaken within Wianamatta Regional Park (see Supporting Document C). The species was not recorded during surveys and the expert report concluded that the potential for the species to occur was low. This reduces the risk of impacts to life-cycle processes and viability of any local population.

Impacts to potential habitat within WSA

Urban capable land impacts on potential habitat for *H. fumana* in the south-east corner of WSA. The impacts are generally around the edges of larger potential habitat polygons, with a total impact of 6.9 ha recorded across WSA. The likelihood that the species occurs within the urban capable footprint is low as:

- The likelihood the species occurred within the potential habitat mapped in the Kemps Creek area was assessed as moderate to low potential
- The species was not recorded during surveys of the area undertaken as part of the strategic biodiversity certification by either the expert (see Supporting Document C) or the ecological consultants

Impacts to potential habitat within GMAC

The urban capable land directly impacts potential habitat for *H. fumana* along the edges of a corridor of habitat that occurs along the outer perimeter of the southern part of GMAC.

This potential habitat currently occurs adjacent to farmland, which means that the impacts of urban development are unlikely to greatly increase edge effects to retained habitat areas or further reduce their viability. Furthermore, the likelihood that the species occurs within the urban capable land is considered low for the following reasons:

- The expert report for *H. fumana* concluded that the species has low potential to occur in GMAC because areas of potential habitat with similar attributes to known sites are highly modified and of limited extent (Miller, 2018b)
- The species was not recorded during surveys of the area undertaken as part of the strategic biodiversity certification by either the expert (see Supporting Document C) or the ecological consultants

The expert identified mostly small areas of 'likely habitat' for the species in the centre and north of GMAC, including at Menangle Park, Milton Part, Kayess Park and Bunbury Curran Creek. These areas are not directly impacted by the urban capable lands. The indirect impacts of the development are considered unlikely to further reduce the viability these areas because these areas are distant from the urban capable lands.

Impacts to potential habitat within Wilton

The urban capable land directly impacts potential habitat for *H. fumana* along the edges of a corridor of habitat that occurs along the outer edge of the northern section of Wilton.

This potential habitat currently occurs adjacent to farmland, which means that the impacts of urban development are unlikely to greatly increase edge effects to retained habitat areas or further reduce their viability. Furthermore, the likelihood that the species occurs within the urban capable land is considered low for the following reasons:

- The expert report concluded that while the species could possibly occur within Wilton, the species is unlikely to occur within the urban capable land because the majority of this area is confined to the Wianamatta Shale-derived soils which, based on current knowledge, is not potential habitat for the species
- The species was not recorded during surveys of the area undertaken as part of the strategic biodiversity certification by either the expert (see Supporting Document C) or the ecological consultants

10.2.3.1(e) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat within the nominated areas is unlikely to affect the ecology of any local population of *H. fumana* because the potential for the species to occur is low.

10.2.3.1(f) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat within the nominated areas is unlikely to fragment or isolate any local population of *H. fumana* because the potential for the species to occur is low.

Two areas of potential habitat will be fragmented within Wianamatta Regional Park as a result of the OSO corridor. The low likelihood of occurrence of *H. fumana* in the area considerably reduces the risk of these impacts.

10.2.3.1(g) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

H. fumana is currently only known from two populations at Moorebank and Bankstown outside the nominated areas. The distance between the populations suggest they are unlikely to interact.

10.2.3.1(h) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The Final Determination and BioNet profile for *H. fumana* identify a range of threats to the species. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Habitat disturbance

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species

and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for *H. fumana* are discussed below for each identified indirect impact.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are recognised as a threat to the species (OEH, 2020). This can relate to fire that is either:

- Too frequent which has the potential to limit recruitment, or
- Too rare which may allow the midstorey to thicken

Inappropriate fire regimes can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for *H. fumana* being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
    - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *H. fumana*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

WEED INVASION

Weeds are recognised as a threat to the species. In particular low shrubs, dense shrubs and smothering grasses (OEH, 2020). Weeds are present in the Strategic Assessment Area and are unlikely to pose a novel threat to *H. fumana*. However, development within the nominated has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *H. fumana*:
    - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
- Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
    - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds

HABITAT DISTURBANCE

Habitat disturbance is a recognised as a threat to the species (OEH, 2020). This relates to mechanisms such as land management practices (e.g. mowing) and uncontrolled vehicle movements.

The Plan incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

The two known populations of *H. fumana* are not within reserves but are managed for conservation – the site at Moorebank is a BioBank/stewardship site, and the site at Bankstown is managed within the airport complex.

There is currently approximately 92 ha of potential habitat for the species mapped within protected areas in the Plan Area. This comprises potential habitat within Wianamatta Regional Park.

Potential habitat also occurs within several Council reserves.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments and actions that will contribute to the recovery of *H. fumana* in the Cumberland subregion. The key commitments and actions relevant to the species are:

- A species-specific commitment to secure 1 offset location of *H. fumana* in conservation lands within the SCA (Commitment 9)
- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for *H. fumana* in the SCA, as there is approximately 1,665.5 ha of mapped potential habitat in the SCA for this species
- Manage weeds in strategic locations in the Cumberland subregion (Commitment 15) to reduce threats to conservation lands secured within the SCA. This includes preparing a Weed Control Strategy to guide and co-ordinate delivery of a weed control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.9 LATHAMUS DISCOLOR

25.9.1 SPECIES BACKGROUND

Lathamus discolor (Swift Parrot) is a medium-sized bright green parrot. It has dark-blue patches on the crown and a red face. It grows to approximately 25 cm in length, with a wingspan of 32-36 cm. It weighs around 65 g (TSSC, 2016a).

Swift Parrots breed in east and south-east Tasmania in summer. During winter, the species migrates to mainland Australia, where it disperses widely through the coast of Victoria, NSW and south-eastern Queensland (Saunders & Tzaros, 2011). In NSW, the species forages in forests and woodlands throughout the coastal and western slopes regions (TSSC, 2016a). The species shows high site fidelity (at both breeding and non-breeding sites) and return to the same locations on an irregular cyclic basis (Saunders & Tzaros, 2011).

Swift Parrots forage on flowers, seeds, fruit, and psyllid lerps in *Eucalyptus* species. The species forages preferentially on larger trees, as larger trees provide more reliable foraging resources than younger trees (Saunders & Tzaros, 2011).

Swift Parrots are adept at foraging in a variety of habitats, from continuous intact vegetation, through to vegetation remnants, scattered trees and vegetation in urban areas (Brereton, Mallick and Kennedy, 2004). It is not a guarantee that more disturbed environments (such as urban or agricultural environments) contain fewer foraging resources than intact vegetation. For instance, within the species' breeding range in Tasmania, Swift Parrots have been observed to forage in higher densities in urban areas than in neighbouring bushland as the trees in urban areas flower more prolifically than the trees in bushland (Hingston and Piech, 2011).

It is thought that trees in disturbed areas including suburban and agricultural environments may produce more food than trees in areas of native vegetation because (Brereton, Mallick and Kennedy, 2004; Hingston and Piech, 2011):

- More isolated trees have greater light penetration in the canopy
- Suburban trees typically have less fire damage
- Farmland/parkland/garden sites are typically managed for soil enrichment
- Agricultural sites are more likely to have more fertile soil than uncleared remnant vegetation which typically occurs on less fertile soil

However, the Swift Parrot's distribution is also strongly influenced by the presence of aggressive competitors (Saunders & Heinsohn, 2008). Aggressive competitors are more likely to be present in disturbed environments. Urban environments also have higher threat densities which reduce habitat suitability for Swift Parrots (Saunders & Tzaros, 2011).

Within NSW, higher densities of Swift Parrots have been recorded in remnant vegetation than in scattered trees or continuous forest (Saunders & Heinsohn, 2008). Saunders & Heinsohn (Saunders & Heinsohn, 2008b) found that the distribution of Swift Parrots in NSW was primarily associated with food availability and the presence of non-aggressive competitors.

Food availability in different regions fluctuates across different years, as a result of variation in climatic conditions. For instance, during periods of drought, higher densities of the species occur in coastal habitats in NSW and Victoria, suggesting these areas function as drought refuge habitat. It is important to maintain a broad range of habitats across the mainland foraging range of the species, as resource availability in any one locality may increase or decrease depending on local conditions each year (Saunders & Tzaros, 2011).

Swift Parrots are usually seen in groups of up to 30 birds, although it may also occur in larger flocks (of hundreds of individuals) around abundant food sources. There are a small number of records of over 1,000 birds (TSSC, 2016a). The population of Swift Parrots was estimated to be approximately 2,000 in 2010. It is likely to have declined since then (TSSC, 2016a).

The species occurs as a single migratory population (Saunders & Tzaros, 2011).

25.9.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

The Swift Parrot has been identified as a potential SAII entity under the DPIE guidelines (Principle 1 of the BC Regulation) (DPIE, 2019), as the species is currently observed, estimated, inferred or reasonably suspected to be in a rapid rate of decline.

The Swift Parrot is a dual credit species. The species credit component occurs in sites mapped as important areas. Mapped important areas do not require survey as it is presumed that the species is present at the site. Any impact from development to important areas is considered to have potential to cause serious and irreversible impacts.

To enable a comprehensive assessment of impacts to this species, this assessment considers impacts to three different types of mapped habitat:

- Important areas (prepared by EES)
- Potential important areas (prepared by the consulting team)
- Potential foraging habitat (prepared by the consulting team)

Assessing mapped important areas, potential important areas and potential foraging habitat provides sufficient context to properly understand the species' occurrence and use of habitat within the nominated areas.

IMPORTANT AREAS

Important areas mapping has been produced by EES as part of the BAM process. Mapping was completed as follows:

Swift Parrot sighting records from 1990-2018 were extracted from BioNet and BirdLife Australia Atlas. Records were checked and cleaned. Records were filtered to include only sightings with five or more birds. A 2km radial buffer was applied.

Important areas were defined by:

1. Areas with five or more records, where observations have occurred over two or more years and are within 2km of one another, or
2. Areas with a single record of 40 or more birds

The NSW State Vegetation Type Map (including draft East Coast classification) was used to select Plant Community Types associated with the swift parrot within the buffers. Any areas of vegetation less than one hectare were excluded.

It is noted that the important areas map prepared by EES will be progressively updated over time.

POTENTIAL IMPORTANT AREAS

The important areas mapping produced by EES only includes Swift Parrot records up to 2018. It is noted that a substantial number of new records for the Swift Parrot were recorded within the Strategic Assessment Area in 2019

which fit the criteria identified in the important areas mapping method, and which are important to consider as part of the assessment process for this species.

Therefore, potentially important areas were identified through replicating the important areas mapping method and including new records from 2019, to indicate the localities which are likely to be included in the important areas mapping by EES when the map is next updated.

POTENTIAL FORAGING HABITAT

It is recognised that the important areas mapping method is based upon the distribution of species' records. However, bias may be present in species' record databases. For instance, localities which are highly likely contain suitable habitat for the species may have access restrictions (either due to land use, such as the Orchard Hills military base, or due to inaccessible terrain features). While it is possible that the Swift Parrot may utilise habitat in these inaccessible localities in large numbers, if sites are inaccessible, then people will not be able to record the species' presence in these localities, and as such there will be an absence of species records in these areas in species databases.

To account for this possible bias, mapped potential foraging habitat for the Swift Parrot has also been considered as part of this assessment. Potential habitat has been mapped using a knowledge-based mapping method and is based on the distribution of PCTs and vegetation condition associated with the species.

The ecosystem credit component occurs in sites mapped as potential foraging habitat. It is noted that impacts ecosystem credit areas are considered unlikely to have potential serious and irreversible impacts.

25.9.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of the Swift Parrot in relation to the subject land is shown in Map 25-7.

RECORDS

As a wide-ranging species, scattered records of the Swift Parrot occur within each nominated area, and throughout the Cumberland subregion. In total, there are 266 records of the Swift Parrot within the Plan area.

Areas of note where larger numbers of Swift Parrots (flocks of 40 or more birds) have been recorded, or where the species has been recorded to return on a periodic basis, include:

- Scattered areas within GPEC, where numerous records identify large flocks of Swift Parrots
- To the north of GPEC, including the Londonderry, North Richmond, and Hawkesbury Heights localities
- To the west of GPEC in the Glenmore Park/Mulgoa locality
- To the east of GPEC near Prospect Reservoir
- To the south of WSA in the Camden and Cobbitty localities
- To the north-west of GMAC near Denman Prospect
- Adjacent to GMAC in the locality of Mount Annan, where recent records from 2019 identify flocks of up to 200 birds
- Just outside the northern boundary of the Strategic Assessment Area in the Cattai locality

IMPORTANT AREAS

Important areas have been mapped by EES to incorporate species' records from 1990-2018. A total of 5,626.1 ha of important areas have been identified within the Strategic Assessment Area, of which 493.4 ha is located within GPEC. Within GPEC, important areas consist of scattered occurrences which comprise of small areas of remnant vegetation within otherwise heavily developed environments.

Within the broader locality of the Cumberland subregion, important areas occur across the following localities:

- To the north of GPEC, including the Londonderry, North Richmond, and Hawkesbury Heights localities
- To the west of GPEC in the Glenmore Park/Mulgoa locality
- To the east of GPEC near Prospect Reservoir
- To the south of WSA in the Camden locality
- To the north-west of GMAC near Denman Prospect

POTENTIAL IMPORTANT AREAS

Potential important areas have been mapped by the consulting team, based on the mapping method used by EES, incorporating more recent records of the species within the Strategic Assessment Area. A total of 731.7 of potential important areas have been identified within the Strategic Assessment Area, of which 80.2 is located within GMAC. Potential important areas occur:

- To the south of WSA in the Cobbitty locality
- Within and adjacent to GMAC in the locality of Mount Annan
- In the north of the Strategic Assessment Area in the Cattai locality

POTENTIAL FORAGING HABITAT

A total of 8,679 ha of potential foraging habitat has been mapped within the nominated areas. Potential foraging habitat broadly aligns with the locations of all remnant vegetation within the Strategic Assessment Area. This area is large because of the broad associations the species has with flowering woodland.

25.9.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM:

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including Swift Parrot, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

A breakdown of avoidance of each identified habitat type is provided below. It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. The amounts of habitat within excluded lands are provided for context only.

In addition, the Plan includes a specific measure for the Swift Parrot to retain large trees (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction.

Important areas

The baseline mapping for this assessment has mapped 83.7 ha of potential foraging habitat for Swift Parrot within the nominated areas (not including excluded lands). Approximately 40.4 ha (48.3 percent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 19.9 ha was avoided for biodiversity purposes
- 20.6 ha was avoided for other purposes

A breakdown of avoidance of important areas across each nominated area is provided in Table 25-25.

Table 25-25: Important areas avoidance outcomes for Swift Parrot

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Important areas (ha)	493.4	409.7	83.7	43.3	19.9	20.6	40.4

Potential important areas

The baseline mapping for this assessment has mapped 2.8 ha of potential important areas for Swift Parrot within the nominated areas (not including excluded lands). None of this area was avoided.

A breakdown of avoidance of potential important areas across each nominated area is provided in Table 25-26.

Table 25-26: Potential important areas avoidance outcomes for Swift Parrot

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential important areas (ha)	80.2	77.5	2.8	2.8	0	0	0

Potential foraging habitat

The baseline mapping for this assessment has mapped 4,514.3 ha of important areas for Swift Parrot within the nominated areas (not including excluded lands). Approximately 3,414.6 ha (75.6 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,568.9 ha was avoided for biodiversity purposes
- 845.8 ha was avoided for other purposes

A breakdown of avoidance of potential foraging habitat across each nominated area is provided in Table 25-27.

Table 25-27: Potential foraging habitat avoidance outcomes for Swift Parrot

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential foraging habitat (ha)	8,679	4,164.8	4,514.3	1099.8	2,568.9	845.8	3,414.6

Avoidance of indirect impacts

Potential indirect impacts to Swift Parrot due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

The Swift Parrot is a migratory species which visits mainland Australia to forage during the winter, before returning to Tasmania in the summer to breed. The species consists of a single population.

Therefore, there is no separate residential population of Swift Parrots within the nominated areas; rather, the parrots which do occur are seasonal visitors from a larger national population of the species.

The proportion of the population of Swift Parrots which utilises habitat within the nominated areas is unknown. However, a record from June 2019 recorded 200 Swift Parrots adjacent to the western boundary of GMAC. Given that the total population size of the species was estimated to be 2,000 individuals (TSSC, 2016a), this record accounts for approximately 10 per cent of the total population of the species. While this record was not located within the nominated areas, it indicates that the wider locality is visited by at least 10 per cent of the total population of the species.

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

The threshold for potential serious and irreversible impacts is any impact to mapped important areas.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

Important areas

A total of 43.3 ha of important areas for Swift Parrot will be directly impacted by development. This is 51.7 per cent of the important areas within the nominated areas (without excluded lands). Impacts are associated with urban development and transport corridors within GPEC only.

Impacted areas mainly involve small, scattered patches of remnant vegetation within already-developed urban areas. The direct impacts of the development on important areas are provided in Table 25-28.

It is noted that of the 43.3 ha of impacts, 13.2 ha of this mapped habitat is mapped over areas of waterbodies, while 4.1 is mapped over areas of exotic vegetation. Therefore, 17.3 ha of this impacted area is not likely to contain real habitat for the Swift Parrot. Total impacts to real habitat within this mapped area is therefore closer to 26 ha.

The impacts to the areas of important areas within GPEC are unlikely to impact the ongoing survival or viability of the Swift Parrot because:

- The areas to be impacted primarily include small, scattered patches of vegetation within already developed urban areas. The long-term viability of vegetation in these highly disturbed localities (which directly influences their long-term capacity to provide foraging habitat for the species) is reduced
- Avoidance of impacts to important areas has prioritised avoidance of larger and more intact areas of vegetation. The vegetation of these areas is more likely to have improved long-term viability, meaning these sites are more likely to be able to continue to provide foraging habitat into the future
- Given the wide-ranging and mobile nature of the species, impacts are unlikely to cause fragmentation or isolation of habitat
- Large trees will be retained during precinct planning, which are preferred foraging resource for the species
- The Plan commits to securing 100 ha for important habitat for the Swift Parrot for conservation purposes to address residual impacts (Commitment 9)

Potential important areas

A total of 2.8 ha of potential important areas for Swift Parrot will be directly impacted by development, with all impacts occurring in a single location within GMAC. This is 100 per cent of the potential important areas within the nominated areas (without excluded lands). Impacts are associated with urban development.

The vegetation which is impacted is a small patch of vegetation located on the edge of urban development. It is therefore unlikely that the vegetation of this site will be fully cleared, and sections will instead be maintained as an APZ. Further, this area of vegetation is known to support an important population of another threatened species, the shrub *Pimelea spicata*. To protect *Pimelea spicata*, Appendix E of the Plan includes a species-specific measure to ensure that management activities within the APZ protect this species. While this measure does not directly relate to protection of species utilised for foraging by the Swift Parrot, it is considered likely that, if management of the APZ in this locality is conducted with conservation of environmental values as a priority, the likelihood of substantial habitat degradation at this site is reduced.

The direct impacts of the development on potential important areas are provided in Table 25-28.

The impacts to the areas of potential important areas within GMAC are unlikely to impact the ongoing survival or viability of the Swift Parrot because:

- The area to be impacted comprises only a small area of vegetation
- Some of the vegetation within this impact area will be retained as part of the APZ, and will benefit indirectly from conservation focused APZ management activities associated with the protection of another threatened species at this site (*Pimelea spicata*)
- The impacts are unlikely to cause fragmentation or isolation of habitat
- Precinct planning will ensure that large trees will be retained, which are preferred foraging resource for the species

- The Plan commits to securing 100 ha of important areas for conservation to address residual impacts (Commitment 9)

Potential foraging habitat

A total of 1099.8 ha of potential foraging habitat for Swift Parrot will be directly impacted by the development. This is 24.4 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development and transport corridors. The direct impacts to potential habitat mainly occur:

- Within GPEC:
  - Within Wianamatta Regional Park and in the locality of Orchard Hills, associated with the development of the Outer Sydney Orbital
  - Within the Mulgoa locality in the south-west corner of GPEC
  - In small, scattered areas of remnant vegetation patches throughout the nominated area
- Within WSA:
  - In the Bringelly and Luddenham localities in the south of the nominated area
  - In smaller scattered areas of remnant vegetation throughout the nominated area
- Within GMAC and Wilton, impacts generally occur to the edges of potential habitat that in most cases remains connected to larger patches of habitat associated with gullies and gorges that run down to the Nepean River or along riparian corridors

The direct impacts of the development on potential foraging habitat are provided in Table 25-28.

The impacts to the areas of potential foraging habitat within GPEC, WSA, GMAC and Wilton are unlikely to impact the ongoing survival or viability of the Swift Parrot because:

- Only a small proportion of potential foraging habitat is directly impacted. The majority of potential foraging habitat has been avoided for biodiversity or other purposes
- The impacts are unlikely to cause fragmentation or isolation of habitat
- Large trees will be retained, which are preferred foraging resource for the species
- The Plan contains a commitment (Commitment 9) to protect 4,410 ha of potential foraging habitat for the Swift Parrot to address residual impacts

Table 25-28: Direct impacts on Swift Parrot

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Important areas (ha)	0	0	0	42.4	0.9	43.3
Potential important areas (ha)	0	2.7	0	0	0.1	2.8
Potential foraging habitat (ha)	149.3	247.4	302.7	127.8	575.3	1099.8

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Indirect impacts

Potential indirect impacts to the Swift Parrot due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(e) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of habitat within the nominated areas is unlikely to affect the ecology of any local population of the Swift Parrot because:

- The majority of habitat has been avoided, and avoidance has prioritised larger, more intact and more important areas of vegetation which are more likely to have long-term viability
- Precinct planning measures will be implemented to retain large trees within urban capable land, which is the preferred foraging habitat for the species
- The Plan commits to securing offsets for the species (4,410 ha of potential foraging habitat, including 100 ha of important habitat) to address residual impacts (Commitment 9)

10.2.3.1(f) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

The Swift Parrot is a migratory visitor to mainland Australia which is highly mobile and has the capacity to cover large distances. The Swift Parrot species occurs as a single population.

Development under the Plan will not result in fragmentation or isolation of the Swift Parrot population.

10.2.3.1(g) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

As the Swift Parrot occurs as a single migratory population (Saunders & Tzaros, 2011), there are no other populations of the species.

10.2.3.1(h) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile, in addition to the Conservation Advice and Recovery Plan for the Swift Parrot identify a range of threats to the species (Saunders & Tzaros, 2011; TSSC, 2016). Where these threats are present in the Plan area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Collision mortality
- Inappropriate fire regimes
- Predation by feral cats

Predation by sugar gliders, competition from honeyeaters, Psittacine Beak and Feather Disease, and illegal wildlife capture and trade are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the threat across the Strategic Assessment Area.

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for the Swift Parrot are discussed below for each identified indirect impact.

<u>Collision mortality</u>

Mortality from collisions with human-made objects in urban areas is an identified threat to the species (TSSC, 2016a). The Conservation Advice states that:

- Continuing urban encroachment into breeding and foraging habitat is increasing the threat
- Collisions are a particular concern in the greater Hobart and Melbourne areas, and the New South Wales central and north coast regions where fatalities have been recorded

There are no records in BioNet of collision mortalities in the Strategic Assessment Area. However, expanding urban development within the nominated areas and development of transport corridors has the potential to increase the threat of collision mortality to the species.

While the threat will remain (and potentially increase), it is unlikely to significantly affect the species within the nominated areas given that:

- Important areas and potential important areas for the species within the nominated areas are already subject of current development
- Larger and more intact areas of potential habitat for the species (such as Orchard Hills) will not be impacted by development

Inappropriate fire regimes

Inappropriate fire regimes, in particular frequent fire, is identified as a threat to the species (Saunders & Tzaros, 2011; TSSC, 2016). Fire can reduce tree flowering events and affect maturation of nectar rich plant species, resulting in reduced foraging resources (Saunders & Tzaros, 2011).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact Swift Parrot habitat. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for the Swift Parrot being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
    - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for Swift Parrot. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the Swift Parrot from increased fire frequency as a result of development. This is because:

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the Swift Parrot and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

Predation by feral cats

Predation from feral cats is identified as a threat to the Swift Parrot in the species recovery plan. New urban development within the nominated areas is very likely to increase the number of domestic cats in the local area, which in turn, may lead to an increase in feral cat populations within adjacent areas of potential Swift Parrot habitat.

Existing land use within the nominated areas and surrounding region includes residential areas and farming, which means cats are unlikely to pose a novel threat to the species in the area. However, the extent of proposed new urban development under the Plan means the threat is likely to be exacerbated.

As outlined in Chapter 15, development controls will be incorporated into DCPs for each nominated area that will:

- Ensure that domestic animals are appropriately contained at urban/bushland interfaces
- Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
- Require appropriate management and control of pest animals relevant to development sites

These measures are considered to adequately mitigate the threat to the species.

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

The Swift Parrot occurs as a single migratory population which visits mainland Australia in the winter to forage, and which returns to Tasmania in summer to breed. It is estimated that there are approximately 2,000 individuals of the species (TSSC, 2016a). Up to 200 parrots have been recorded at a time in the vicinity of the nominated areas, indicating that at least 10 per cent of the population of the species visits the locality.

An estimate of the important areas for the Swift Parrot in protected lands in the area covered by the Plan is 1,025.2 ha.

An estimate of the potential important areas for the Swift Parrot in protected lands in the area covered by the Plan is 241.1 ha.

An estimate of the potential foraging habitat for the Swift Parrot in protected lands in the area covered by the Plan is 6,699.9 ha.

The Swift Parrot has also been recorded within several of the following protected lands within and outside the Cumberland subregion, including:

- Scheyville National Park
- Castlereagh Nature Reserve
- Royal National Park
- Heathcote National Park
- Dharawal National Park
- Upper Nepean State Conservation Area
- Nattai National Park
- Blue Mountains National Park

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of the Swift Parrot in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments and actions relevant to the species are:

- A commitment to protect 4,410 ha of potential foraging habitat, including 100 ha of important habitat, for the Swift Parrot (Commitment 9)
- A mitigation measure within Appendix E of the Plan to retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction
- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential foraging habitat for the Swift Parrot in the SCA, as there is approximately 17,178 ha of mapped potential foraging habitat in the SCA for this species
- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion

- The introduction of development controls to manage impacts of domestic and pest animals

25.10 LITORIA AUREA

25.10.1 SPECIES BACKGROUND

Green and Golden Bell Frog (*Litoria aurea*) is a relatively large, dull, olive to bright emerald-green frog.

The species requires different habitats for foraging, breeding, over-wintering, and dispersal. The species also uses certain habitats on a periodic or seasonal basis (DEWHA, 2009b). Habitat comprises one or more water bodies, and associated terrestrial habitats with grassy areas and low vegetation, although the species tends not to disperse far from waterbodies into more terrestrial non-breeding habitats (DEWHA, 2009c; Lemckert, 2019). The species has been found in a wide range of water bodies except those that are fast flowing and the species can occur in disturbed habitats (DEWHA, 2009b).

Breeding habitat includes water bodies that are still, shallow, temporary, unshaded, with aquatic plants and free of mosquito fish. Ephemeral water bodies are important habitat for the species as they can provide habitat stepping stones between otherwise disconnected areas and they are less likely to contain mosquito fish (DEWHA, 2009b).

Records suggest that Green and Golden Bell Frog is highly mobile and moves between breeding sites. Movements of up to 5 km may be common and the frog may disperse up to 10 km (DoEE, 2018a). Connectivity between habitat sites is vital as the species exhibits a 'metapopulation structure', which relies on dispersal between 'local' populations within a larger 'metapopulation'. The species is more likely to be present, and habitat more likely to be important, where:

- Multiple suitable breeding sites are within a close enough proximity for individuals to migrate between them
- Multiple non-breeding water bodies are present in an area and within close enough proximity to allow migration between them (and breeding sites) with relative ease
- The connectivity of breeding and non- breeding habitat contains vegetation and shelter that facilitates migration
- There are other individuals occupying waterbodies in close proximity (Lemckert, 2019)

Breeding of the Green and Golden Bell Frog occurs generally between September and February after heavy rains or storms, and spawn is laid among aquatic vegetation (DEWHA, 2009b). The species has high fecundity and clutch sizes have been known to contain between over 2000 to 11,000 eggs (DEWHA, 2009b).

Records of the species in NSW are widely separated and isolated (OEH, 2019f). Approximately 30 populations are known. The largest populations of the species are located in Sydney and the Shoalhaven and mid north coast areas (OEH, 2019f). Most populations have fewer than 20 adults. Over 1,000 individuals have been recorded at Homebush, Kooragang Island and Broughton Island (DoEE, 2018a).

Nearly all known populations of Green and Golden Bell Frog are located with 10 km of the coast or saline waterways. This is likely due to the species being susceptible to the amphibian chytrid fungus, as the fungus is intolerant of salt. These locations therefore provide some refuge from the impacts of chytrid (Lemckert, 2019).

25.10.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

Green and Golden Bell Frog is being assessed as a candidate species credit species for all four nominated areas.

The species has been identified as a potential SAII entity in accordance with the requirement of section 10.2.1.4 of the BAM because of its very high susceptibility to the disease Chytrid fungus (Principle 4 of the BC Regulation).

An expert report has been prepared for the Green and Golden Bell Frog (Lemckert, 2019).

The expert report involved:

- Targeted surveys within the most likely areas of potential habitat for this species
- Identification of potential habitat within the nominated areas

25.10.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of Green and Golden Bell Frog in relation to the subject land is shown in Map 25-8.

A total of 13,146 records for the Green and Golden Bell Frog occur within the Cumberland subregion. The majority (greater than 95 per cent) occur in the eastern third of the subregion outside the nominated areas (Lemckert, 2019).

In relation to the records in the subregion, the expert report concluded that:

- Few records occur in the Cumberland subregion, and it appears the species has never been common in this area, reflecting the fact that the region is over 10 km from the coast where chytrid fungus is more likely to be present
- The majority of records are from prior to 1990, indicating that most populations are likely to now be extinct. This is consistent with the pattern of declines noted for the species by Mahony et al (2013), who noted that populations rarely persist more than 10 kilometres from the coast (i.e. east of the nominated areas)

Records of the species within the nominated areas are limited. There are:

- 12 records within GPEC. The records primarily occur around St Marys and Ropes Creek. Surveys of this site have been completed since public exhibition and no individuals of the species were identified at this site. Further, habitat features of the site were considered suitable for shelter and dispersal only, and not suitable for breeding. Therefore, it is considered unlikely that this population is still present at this site. See Supporting Document I for further information regarding the surveys and results
- Three records within GMAC, all of which occur at Blair Athol. The expert report concluded that the records at Blair Athol are likely to be from individuals that escaped a captive colony and the population is no longer likely to persist in that location (Lemckert, 2019). However, since that time, further records have since become available, suggesting that the population may be present and self-sustaining
- One record in WSA. This record is considered to relate to a single and transient individual dispersing from a non-natural population of the species in Riverston (with habitats created by a 'backyard breeder'), and does not equate to a natural or self-sustaining population of the species (Dr Frank Lemckert pers. comm.)

There are no records in Wilton.

As part of the EPBC assessment for the development, two important populations of Green and Golden Bell Frog were identified in proximity to the nominated areas:

- A population at Gow Park in Mulgoa, approximately 2.4 km south of the nearest urban capable land within GPEC. This population was recorded in 1999 in a non-permanent creek
- A population along the eastern boundary of the Strategic Assessment Area, approximately 17 km east of WSA

The population around St Marys and Ropes Creek occurs within the urban capable land.

Approximately 1,654.5 ha of potential habitat for Green and Golden Bell Frog has been identified within the nominated areas. This occurs GPEC and GMAC. The majority of potential habitat occurs around St Marys between Ropes Crossing in the north and Minchinbury in the south. A smaller area occurs around Blair Athol.

25.10.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM:

10.2.3.1(a) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including Green and Golden Bell Frog, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

There are no known populations of the Green and Golden Bell Frog within the nominated areas. It is noted that surveys undertaken since public comment did not find the species in GPEC, and the new record of the species within WSA is not considered to be that of a natural, self-sustaining population.

The baseline mapping for this assessment has mapped 24.6 ha of potential habitat for Green and Golden Bell Frog within GPEC and GMAC (not including excluded lands). Approximately 11.3 ha (45.8 per cent) of this was avoided as part of

the design of the urban capable land and transport corridors (not including excluded lands). All of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 25-29.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-29 shows the amounts of habitat within excluded lands for context only.

Table 25-29: Avoidance outcomes for Green and Golden Bell Frog

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	1,654.5	1,629.9	24.6	13.3	11.2	<0.1	11.3

Avoidance of indirect impacts

Potential indirect impacts to Green and Golden Bell Frog due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(b) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Direct impacts

Development within GPEC will directly impact records of a historical population of the Green and Golden Bell Frog associated with Ropes Creek. This population comprises 6 BioNet records made between 1998 and 2012. The development will impact an area associated with one of these records made in 1998. The impact is associated with urban development.

At the time of public exhibition, it was considered likely that the population at this locality could still be present, and targeted surveys of the site had not been completed. The draft Plan at this stage contained a species-specific measure to undertake surveys within potential habitat along Ropes Creek to determine if the species was still present, and if confirmed to be present, to avoid, protect and enhance key habitat features of the site.

Targeted surveys of Ropes Creek have since been completed. The surveys were carried out in December 2020 and January 2021. The surveys did not find any individuals of the species present at the site. Potential shelter and dispersal habitat for the species was identified, yet the habitat of the locality was considered unlikely to be suitable for breeding. Further information regarding the species survey is available in Supporting Document I.

Given that the riparian habitat available for the species at this site is suitable for shelter and dispersal only, and that the species was not found to be present during survey, the risk posed to the species of impacts to this habitat is considered to be very low. It is recognised that the Plan includes a species-specific commitment (Commitment 3) to avoid and minimise impacts to the Green and Golden Bell Frog and its habitat within certified major transport corridors through detailed planning and design. This includes avoiding areas of potential habitat connectivity within riparian corridors where possible. This measure will help to minimise potential impacts to riparian habitat for the Green and Golden Bell Frog within GPEC.

A smaller area of potential habitat occurs around Blair Athol between the Hume Motorway and Campbelltown in GMAC. There is potential that the species may occur in GMAC, as recent records at Blair Athol suggest a population may be persisting at this site. There will not be any direct impacts to this population.

Indirect impacts

Potential indirect impacts to Green and Golden Bell Frog due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(c) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for Green and Golden Bell Frog.

10.2.3.1(d) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

The area of potential habitat within and around the Ropes Creek corridor at St Marys in GPEC covers:

- The locations of known records
- The riparian corridor joining those records
- A buffer of 1,000 m around the riparian corridor and records that could be used by the species for foraging, shelter, breeding and as migratory habitat as individuals move between water bodies and riparian corridors (Lemckert, 2019)

Approximately 13.3 ha of potential habitat will be directly impacted by the development within GPEC along Ropes Creek. This is about half of the potential habitat in the nominated areas (without excluded lands). This includes:

- 1.9 ha of aquatic/riparian habitat
- 7.11 ha of terrestrial habitat less than 200 m from aquatic habitat
- 4.4 ha of terrestrial habitat greater than 200 m from aquatic habitat

The direct impacts of the development on Green and Golden Bell Frog are provided in Table 25-30.

Table 25-30: Direct impacts on Green and Golden Bell Frog^

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	0	0	0	11	2.3	13.3^

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

^ Note that this total impact of 13.3 ha includes:

- 0.06 ha of impact on non-native vegetation (see Chapter 24)
- 0.62 ha of impact on a non-vegetated waterbody (see Chapter 24)
- 5.63 ha of impact on an existing urban area comprising buildings and roads ('man-made structures' - see Chapter 24)

The majority of habitat loss within GPEC is associated with the site of the current St Marys Rugby League Club adjacent to the Ropes Creek corridor and includes at least two mapped water bodies. A smaller impact occurs to the north-west of St Marys Rugby League Club associated with the OSO.

The development is unlikely to cause fragmentation or isolation of potential habitat at Ropes Creek because the area impacted occurs at the edge of the area of potential habitat (excluding areas that are already developed) and distant from the riparian corridor of Ropes Creek, as well as being adjacent to existing urban development, including two major roads. The corridor of habitat along the riparian corridor at Ropes Creek will therefore be maintained.

Indirect impacts

Potential indirect impacts to Green and Golden Bell Frog due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(e) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (b) and (d) above, the Plan is will not result in direct impacts on known populations of the species.

10.2.3.1(f) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the development is unlikely to cause fragmentation or isolation of any local population because impacts occur at the edge of the area of potential habitat and distant from the riparian corridor of Ropes Creek. The corridor of habitat along the riparian corridor at Ropes Creek will be maintained.

10.2.3.1(g) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Potential habitat for the Green and Golden Bell Frog within GPEC and GMAC occurs towards the western edge of the distribution of the species in the Cumberland subregion. The potential population at Ropes Creek is disjunct from the majority of known records which generally occur over 20 km to the east.

10.2.3.1(h) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile and Conservation Advice for the Green and Golden Bell Frog identify a range of threats to the species. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Changes to the structure and diversity of aquatic vegetation
- Changes to hydrology and water quality
- Intensification of public access to habitat
- Predation by foxes, cats, dogs, and rats
- Inappropriate fire regimes
- Infection with amphibian chytrid fungus
- Road mortality

Predation of eggs and tadpoles, predation by exotic fish, interaction with cane toads and grazing are also identified as potential threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for the Green and Golden Bell Frog are discussed below for each identified indirect impact.

CHANGES TO THE STRUCTURE AND DIVERSITY OF AQUATIC VEGETATION

Changes to the structure and diversity of aquatic vegetation from weed invasion is a key threat to the Green and Golden Bell Frog. Weeds are already present within the Strategic Assessment Area. However, urban and transport development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The species is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occurs adjacent to known populations or habitat, in particular adjacent to the OSO and close to North St Marys along Ropes Creek in GPEC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for the Green and Golden Bell Frog:
    - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans

  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
  - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
  - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
  - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds

The package of measures in the Plan is expected to adequately manage the risk posed to the Green and Golden Bell Frog from invasive weeds. This is because:

- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

CHANGES TO HYDROLOGY AND WATER QUALITY

A reduction in water quality and changes to hydrology are recognised as a principal threat to the species (DEWHA, 2009c). Key issues relate to changes to drainage patterns and stormwater runoff, soil erosion and sedimentation and increased pollutants.

Development under the Plan has the potential to alter water quality and hydrology in areas of known and potential habitat for the Green and Golden Bell Frog. The areas at risk include habitat for the species with Ropes Creek where development of the Western Sydney Freight Line (transport corridor to the east of WSA) intersects an upstream section of the creek.

The Plan incorporates a range of general measures to mitigate the risks associated with changes to hydrology. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement measures to manage hydrological impacts, including in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage, and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures for major transport corridors based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines (NSW RTA and NGH Environmental Consultancy, 2011). These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed, and operated in a way that avoids and minimises any potential impacts to habitat for the species
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

INTENSIFICATION OF PUBLIC ACCESS TO HABITAT

Intensification of public access to habitat is identified as a threat to the species. However, populations of the Green and Golden Bell Frog adjacent to or within proximity of proposed development are already subject to this threat as they are located within highly urbanised areas. Implementation of the Plan is unlikely to change the current level of disturbance.

The Plan incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations. It is noted that 91.4 ha of potential habitat for the Green and Golden Bell Frog is contained within the three conservation reserves proposed by the Plan
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the species from increased public access to habitat areas as a result of development. This is because:

- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

PREDATION BY CATS AND OTHER PEST ANIMALS

Predation by cats and other pest animals is recognised as a threat to the Green and Golden Bell Frog. New urban development under the Plan is likely to increase the number of domestic cats in the local area. However, areas of habitat within proximity of proposed development already occur within highly urbanised areas. Any increase in the risk of predation from cats on populations of the Green and Golden Bell Frog as a result of the Plan is expected to be minimal.

The Plan also incorporates a range of measures to manage this issue across throughout the nominated areas. In summary, these include:

- A commitment (Commitment 16) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
    - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
    - Preparation of a Pest Animal Control Implementation Strategy
    - A process to enter into written agreements with delivery partners to implement the pest animal control program
    - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans

- Incorporation of development controls into DCPs for each nominated area that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are identified as a potential threat to the Green and Golden Bell Frog (DoE, 2014b).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for the Green and Golden Bell Frog being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
  - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
  - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the Green and Golden Bell Frog. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

INFECTION WITH AMPHIBIAN CHYTRID FUNGUS

Amphibian chytrid fungus, which causes the infection known as chytridiomycosis, is likely to impact on populations of the Green and Golden Bell Frog. The threat to the species from chytrid fungus is not well understood, with the risk of extinction from the disease categorised as low to moderate (DEWHA, 2009b; DoEE, 2016). However, the suitability of habitat is influenced by the presence of chytrid fungus.

Chytrid fungus is already present in the Cumberland subregion, although there may be pockets of disease free areas that are inhospitable to the growth of the disease (for example, due to salinity levels or elevated concentrations of trace metals). The potential for dispersing chytridiomycosis in wild frog populations increases with urbanisation around

streams. This comes from growing potential for human interaction, more water flow (urban run-off) and reduced optimal habitat. Increased risks associated with development under the Plan are minimal, however, as habitat areas are already highly urbanised.

The *Cumberland Plain Conservation Plan Guidelines for Infrastructure* contain the following species-specific measure: "For areas where the Green and Golden Bell Frog is confirmed, incorporate best practice site hygiene protocols to manage the potential spread of chytrid fungus". This measure will address the potential impacts of chytrid fungus to the species from development of essential infrastructure on avoided land.

Further, Appendix E of the Plan contains a range of measures to incorporate best practice site hygiene protocols for development on urban capable land and development within the transport corridors across all nominated areas. While the Green and Golden Bell Frog is not specifically identified as a target species for these measures, the species will nonetheless benefit from these controls which will minimise the risk of spread of chytrid fungus.

The Plan further incorporates a range of general measures to manage the risks associated with chytrid fungus. In summary, these include:

- A commitment (Commitment 18) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
    - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
    - Entering into written agreements with delivery partners to implement priority disease control programs
- Incorporation of development controls into DCPs for each nominated area to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of chytrid fungus

The package of measures in the Plan is expected to adequately manage the risk associated with chytrid fungus because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

ROAD MORTALITY

Road mortality is identified as a potential threat to the Green and Golden Bell Frog (DoE, 2014b). This is not a novel threat to the species within the Strategic Assessment Area as roads have already been developed in proximity to habitat areas. However, implementation of the Plan will lead to new roads and an increase in the volume of cars on existing roads within nominated areas. The main area of concern is the development of the Outer Sydney Orbital downstream of habitat associated with the Ropes Creek corridor

The Plan includes a species-specific measure (Commitment 3) to avoid and minimise impacts to the Green and Golden Bell Frog and its habitat within certified major transport corridors through detailed planning and design. This includes avoiding areas of potential habitat connectivity within riparian corridors where possible. This measure will minimise the risk of road mortality to the species.

Further, Commitment 6 of the Plan contains the following action (Action 1 d): "identify potential design options for major watercourse crossings to reduce disruption to connectivity and the risk of fauna vehicle strikes".

These measures are considered to adequately address any potential increased threat from road mortality due to implementation of the Plan.

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 340.6 ha of potential habitat mapped within protected areas within the area covered by the Plan. This includes potential habitat within:

- Wianamatta Regional Park
- Agnes Banks Nature Reserve

Populations are known to occur in several conservation reserves outside the Cumberland subregion.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of Green and Golden Bell Frog in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments and actions relevant to the species are:

- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for Green and Golden Bell Frog in the SCA, as there is approximately 462.3 ha of mapped potential habitat in the SCA for this species
- A species-specific measure (as part of Commitment 3) to avoid and minimise impacts to the Green and Golden Bell Frog and its habitat within certified major transport corridors through detailed planning and design
- Manage pest animals in strategic locations in the Cumberland subregion (Commitment 16) to reduce threats to conservation lands secured within the SCA. This includes preparing a Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Support new or existing programs to control key diseases affecting TECs and species in the Cumberland subregion (Commitment 18)

25.11 MELALEUCA DEANEI

25.11.1 SPECIES BACKGROUND

Melaleuca deanei is a flaky-barked shrub with narrow pointed leaves and white flowers which grows to 3 m tall (DoEE, 2018a).

The species flowers in mid-October to December. Produces seeds infrequently and relies on clonal reproduction. Seeds can be held for up to 15 years, until fire, frost or drought triggers their release (DoEE, 2018a).

Longevity of individuals can be 100 years (NSW DECCW, 2010).

M. deanei inhabits ridgetop woodland and wet heath, on sandstone and sandy soils (DoEE, 2018a; OEH, 2019d). The majority of records come from ridgetop woodland (OEH, 2019d). *M. deanei* is associated with sandy loam soils which are low in nutrients (NSW DECCW, 2010).

Records occur primarily in the Ku-ring-gai/Berowra and Holsworthy/Wedderburn areas. Isolated records also occur in Springwood, Wollemi National Park, Yalwal and Central Coast areas. It is known to occur in the Cumberland IBRA subregion (OEH, 2019d). More than 50 per cent of all populations are protected in nature reserves or national parks (NSW DECCW, 2010).

As of 1993, the species was known from 94 populations, of which very few were considered reproductively viable. In 1993, it was estimated that there were 1,000-3,000 individuals of this species though this was likely as a ramet (stem) count (DoEE, 2018a). However, recent genetic research suggests that the species' population size may be much smaller than previous estimates (Douglas, 2019).

Population distribution is fragmented (DoEE, 2018a).

25.11.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

M. deanei is being assessed as a candidate species credit species for Wilton and GMAC. The species has been also identified as a potential SAII entity under the EES guidelines (Principle 4 of the BC Regulation) (OEH, 2017g), as it is a species which is unlikely to respond to management and is therefore irreplaceable.

25.11.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of *M. deanei* in relation to the subject land is shown in Map 25-9.

RECORDS

There are three populations which have been identified within and in proximity to the nominated areas.

One population (population 77) is located adjacent to the confluence of Allens Creek with Stringybark Creek, within Wilton. This population occurs within the boundary of a previously approved development under the EPBC Act (EPBC 2014/7400).

Both of the other populations (population 520 and population 463) occur to the north-east of Campbelltown, within the footprint of the proposed Georges River Koala Reserve.

It is noted that numerous additional records of this species occur in remnant vegetation adjacent to the nominated areas, in areas to the south of Wilton and to the east of Appin, Campbelltown and Macquarie Fields.

POTENTIAL HABITAT

The baseline mapping for this assessment has mapped 2,321.4 ha of known and potential habitat within two nominated areas (GMAC and Wilton). Habitat in these areas is well-connected, and strongly corresponds to the locations of wooded areas in these localities. There is no habitat mapped within GPEC or WSA.

25.11.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including *M. deanei*, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The only records of *M. deanei* within the nominated areas occur within excluded land in Wilton, and subsequently are not located within urban capable land under the Plan.

The baseline mapping for this assessment has mapped 1,750.3 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 1,644.1 ha (93.9 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,545.2 ha was avoided for biodiversity purposes.
- 98.9 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-31.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-31 shows the amounts of habitat within excluded lands for context only.

Table 25-31: Avoidance outcomes for *M. deanei*

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	2,321.4	571.1	1,750.3	106.2	1,545.2	98.9	1,644.1

Avoidance of indirect impacts

Potential indirect impacts to *M. deanei* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within the nominated areas will not directly impact on any records or known populations of *M. deanei.*

Potential indirect impacts to *M. deanei* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

No threshold has been established for *M. deanei.*

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

There will be no direct impacts to any known populations of *M. deanei* under the Plan.

Approximately 106.2 ha of potential habitat for the species will be lost. This is 6.1 per cent of the potential habitat in the nominated areas (not including excluded lands). The loss of potential habitat occurs within GMAC and Wilton.

The direct impacts of the development are associated with urban development, and primarily impact the fringes of mapped potential habitat corridors within GMAC and Wilton. Impacts in these areas will not result in habitat fragmentation as impacts are located along existing edges of habitat which occur adjacent to cleared areas.

A section of potential habitat within the urban capable land which could be accessed as part of this biodiversity certification process was surveyed and the species was not observed. It is generally considered unlikely that potential habitat in this area contributes to the ongoing survival or viability of the species more broadly.

The direct impacts of the development on *M. deanei* are provided in Table 25-32.

Table 25-32: Direct impacts on *M. deanei*

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	45.4	60.8	0	0	0	106.2

Indirect impacts

Potential indirect impacts to *M. deanei* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat areas within Wilton and GMAC is unlikely to affect the ecology of *M. deanei* in the locality because:

- There is a low likelihood the species occurs within potential habitat which will be directly impacted under the Plan
- The loss of potential habitat will not affect key life-cycle processes of the species, which regenerates through both seed production and vegetative growth
- Potential habitat will not be fragmented by development

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat areas within Wilton and GMAC will not result in fragmentation of potential habitat nor populations of *M. deanei*.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Known populations within/near the nominated areas include:

- Population 77 within Wilton, which is located within excluded lands
- Population 520 and population 463 which occur to the north-east of Campbelltown, within the footprint of the proposed Georges River Koala Reserve

These populations occur along the eastern boundary of a stronghold region for the species, which ranges between the Holsworthy locality in the north through to the Appin region in the south. It is noted that the Holsworthy Military Reserve (to the north-east of GMAC) it contains 17 per cent of the known population outside formal conservation reserves (NSW DECCW, 2010).

Potential habitat within Wilton and GMAC occurs in the approximate centre of the species' total geographic extent.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile (OEH, 2019d), Recovery Plan (NSW DECCW, 2010) (and other key documents) for *M. deanei* identify a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in key species documents) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes and mechanical methods of bushfire fuel reduction
- Inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access and rubbish dumping
- Weed invasion

Low fecundity and viability, hybridisation, and trampling/plant damage due to army training exercises have also been identified as key threats. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats within the nominated areas.

There are three known populations of *M. deanei* within or in close proximity to the nominated areas:

- Population 520 and population 463 occurs to the east of GMAC within the footprint of the proposed Georges River Koala Reserve. These populations are not considered at risk of indirect impacts under the Plan due to their distance from urban capable land and the fact that the site will be managed for conservation purposes
- Population 77 occurs within Wilton within the offset site of an existing development approval and is managed in accordance with that approval. Management of the site includes measures to minimise indirect impacts, including fencing to restrict access, and preparation of an environmental management plan to deal with pressures to the population. Overall, population 77 is not considered to be at risk of indirect impacts under the Plan

The following assessments therefore consider the potential impacts of development under the Plan upon mapped potential habitat for *M. deanei.* The areas which are most at risk of impact include mapped habitat within Wilton and the southern portion of GMAC, which occurs close to urban capable lands.

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for *M. deanei* are discussed below for each identified indirect impact.

INAPPROPRIATE FIRE REGIMES AND MECHANICAL METHODS OF BUSHFIRE FUEL REDUCTION

Inappropriate fire regimes are an identified threat to *M. deanei* (NSW DECCW, 2010). Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the following mechanisms:

- Increased fire frequency due to arson and accidental lighting of fires

- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

It is additionally noted that mechanical bushfire reduction methods of habitat in close proximity to urban and other kinds of development pose a risk to *M. deanei* (NSW DECCW, 2010).

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for *M. deanei* being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
    - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *M. deanei*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to *M. deanei* from altered fire regimes as a result of development. This is because:

- Avoided land and the SCA will be protected under the SEPP (Strategic Conservation Planning)
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *M. deanei* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *M. deanei* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas (it is noted there is 7,466.4 ha for *M. deanei* mapped within the SCA. This includes 1,837.9 ha of potential habitat for *M. deanei* is contained within two of the Plan's proposed reserves)

INAPPROPRIATE HABITAT DISTURBANCE FROM CONSTRUCTION AND MAINTENANCE OF TRACKS AND EASEMENTS, UNRESTRICTED ACCESS AND RUBBISH DUMPING

Impacts relating to construction and maintenance of tracks and easements, unrestricted site access and rubbish dumping have been identified as threats to *M. deanei* (NSW DECCW, 2010). Areas most at risk included areas of mapped potential habitat within Wilton and GMAC.

Appendix E of the Plan includes a species-specific measure to consult with land managers of land containing known populations or habitat for *M. deanei* to mitigate indirect impacts from habitat disturbance during construction and operation of the development, including controlling public access, managing maintenance activities such as mowing and weed control, and managing rubbish dumping. This measure applies to GMAC and Wilton and will be implemented via consultation with local councils and other public agencies.

The Plan further incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations. It is noted that 1,837.9 ha of potential habitat for *M. deanei* is contained within two of the Plan's proposed reserves, and two important populations of the species occurs within the Georges River Koala Reserve
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to *M. deanei* from inappropriate habitat disturbance as a result of development. This is because:

- A species-specific measure will require consultation with land managers to ensure protection of *M. deanei* from inappropriate habitat disturbance
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

WEED INVASION

Inappropriate fire regimes are an identified threat to *M. deanei* (NSW DECCW, 2010). Areas most at risk of weed invasion due to development under the Plan included areas of mapped potential habitat within Wilton and GMAC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area (SCA). This includes a number of actions, of which the following are the most relevant to the outcome for *M. deanei*:
    - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
    - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies

  - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds

The package of measures in the Plan is expected to adequately manage the risk to *M. deanei* from the increased risk of weeds associated with development. This is because:

- Avoided land and the SCA will be protected under the SEPP (Strategic Conservation Planning)
- There is a commitment (Commitment 15) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development, and operational stages of development

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

In 2010, more than 50 per cent of all known occurrences of the species occurred within NSW National Parks. Since 2010, the species has achieved greater protection, as follows (Douglas, 2019):

- Gazettal of the Upper Nepean State Conservation Area has increased protection to two known large populations
- Gazettal of the Dharawal National Park has increased protection of numerous occurrences
- Gazettal of Berowra Valley National Park has increased protection to numerous occurrences. It is noted that, in 2010, the area covered by this National Park contained 17 per cent of the total known sites of the species

There is currently approximately 1,607.3 ha of potential habitat mapped within protected areas within the Strategic Assessment Area.

It is also noted that a, outside of formal conservation reserves, a large population occurs in Holsworthy Military Reserve. This population contains 17 per cent of the known population outside formal conservation reserves (NSW DECCW, 2010).

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of *M. deanei* in the Cumberland subregion. Several commitments are described in more detail the sections above.

Key commitments relevant to the species are:

- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for *M. deanei* in the SCA, as there is approximately 7,466.4 ha of mapped potential habitat in the SCA for this species
- Manage weeds (Commitment 15) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within SCAs. This includes preparing a Weed Control Strategy to guide and co-ordinate delivery of a weed control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
  - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
  - Preparing a Fire Management Strategy to guide and co-ordinate fire management
- Minimise habitat disturbance (Commitments 20 and 26), including a species-specific measure which requires consultation with land managers to ensure protection of *M. deanei* from inappropriate habitat disturbance

25.12 MICROMYRTUS MINUTIFLORA

25.12.1 SPECIES BACKGROUND

Micromyrtus minutiflora is a slender spreading shrub that grows to 2 m high with solitary flowers and white petals (DEWHA, 2008).

The species flowers sporadically from June to March. Response to disturbance (such as fire or mechanical) is uncertain. Regeneration may occur as a result of re-sprouting, or germination of seeds stored within the soil (OEH, 2019i).

M. minutiflora inhabits Scribbly Gum Woodland, Cooks River/Castlereagh Ironbark Forest, Shale/Gravel Transition Forest, open forest on tertiary alluvium and consolidated river sediments (DEWHA, 2008; OEH, 2019i).

The species is endemic to the western parts of the Cumberland subregion in the Richmond-Castlereagh area and has a highly restricted distribution. The distribution overlaps with CRCIF and Castlereagh Scribbly Gum Woodland.

In 2002 there were 11 known populations with approximately 1,800 individuals across the Blacktown, Hawkesbury and Penrith Local Government Areas. In 1997, there were over 1,160 individuals in the Australian Defence Industries site and 500 individuals at Marsden Park site. Populations range from fewer than 50 plants to over 1,000 (DEWHA, 2008).

25.12.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

Micromyrtus minutiflora is being assessed as a candidate species credit species for GPEC and WSA nominated areas.

The species has been identified as a SAII entity in accordance with the requirement of section 10.2.1.4 of the BAM because it has a very highly restricted geographic distribution, which triggers Principle 3 of the BC Regulation.

25.12.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of *M. minutiflora* in relation to the subject land is shown in Map 25-10.

The majority of records and potential habitat for *M. minutiflora* occur to the north of the nominated areas. GPEC and WSA occur within the southern extent of the species stronghold in the Castlereagh and Londonderry areas.

There are several records of the species within GPEC located in the vicinity of Wianamatta Regional Park in the Ropes Crossing area. There are no records of the species within WSA.

There are no records of *M. minutiflora* within the urban capable lands of GPEC and WSA. The important population on the edge of Wianamatta Regional Park in the Ropes Crossing area occurs approximately 1.5 km from the nearest urban capable land.

The species was targeted during surveys within the nominated areas but was not recorded.

Approximately 256.4 ha of potential habitat for *M. minutiflora* has been identified within GPEC and WSA. The majority of potential habitat occurs within the Wianamatta Regional Park in the northern part of GPEC, however surveys confirmed the species was not present within the OSO alignment. A smaller patch of potential habitat has been mapped in Orchard Hills in the middle part of GPEC and around Kemps Creek in WSA. The remaining habitat areas exists mainly as scattered and isolated habitat patches across the eastern half of GPEC.

25.12.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including *M. minutiflora*, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The population of *M. minutiflora* within GPEC occurs outside the urban capable land and has been avoided.

The baseline mapping for this assessment has mapped 69 ha of potential habitat for *M. minutiflora* within the nominated areas (not including excluded lands). Approximately 37.3 ha (54 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 37.1 ha was avoided for biodiversity purposes
- 0.2 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-33.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-33 shows the amounts of habitat within excluded lands for context only.

Table 25-33: Avoidance outcomes for *M. minutiflora*

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	256.4	187.4	69	31.7	37.1	0.2	37.3

Avoidance of indirect impacts

Potential indirect impacts to *M. minutiflora* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within GPEC and WSA will not directly impact on any records or known populations of *M. minutiflora.*

Potential indirect impacts to *M. minutiflora* potential habitat due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for *M. minutiflora.*

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 31.7 ha of potential habitat for *M. minutiflora* will be directly impacted by the development. This is 45.9 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development. The direct impacts mainly occur:

- To scattered patches of potential habitat at Orchard Hills in the central part of GPEC, which will be impacted by urban development
- To potential habitat within the alignment of the M7/Ropes Crossing Link Road in northern GPEC
- To potential habitat within the Kemps Creek area in WSA associated with urban development

An area of potential habitat within the Wianamatta Regional Park in the northern part of GPEC is bisected by the corridor for the Outer Sydney Orbital (OSO). Survey confirmed the species was absent with the road corridor, however potential habitat is mapped either side of the OSO and would be fragmented by the proposed development.

The direct impacts of the development on *M. minutiflora* are provided in Table 25-34.

Table 25-34: Direct impacts on *M. minutiflora*

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	0	0	8.3	10.6	12.8	31.7

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Impacts to habitat in northern GPEC

The M7/Ropes Crossing Link Road impacts on 4.4 ha of potential habitat along the northern boundary of GPEC. Although not directly impacting on mapped habitat, the OSO corridor will lead to fragmentation of potential habitat within Wianamatta Regional Park, leading to a number of smaller, isolated patches of vegetation. This fragmentation may increase impacts associated with edge effects (primarily weeds) and this has the potential to compromise the suitability of remaining habitat areas directly adjacent to development.

The species was confirmed absent within the OSO corridor during project surveys, and the likelihood that the species occurs within lands adjacent to the corridor is considered low given:

- The area forms part of a Regional Park which is managed by the NSW NPWS and would be well traversed
- The species is relatively easy to identify when it is in flower

This low likelihood of occurrence considerably reduces the risk of impacts to *M. minutiflora* on key life-cycle processes.

Impacts to habitat at Orchard Hills

The loss of potential habitat at Orchard Hills is associated with small, scattered patches of habitat that are currently surrounded by houses and farmland. The extent of cleared land in the area means that impacts are unlikely to increase edge effects to retained habitat areas or further reduce their viability.

Impacts to habitat in WSA

Impacts to potential habitat within WSA are restricted to the Kemps Creek area and are associated with urban capable development. The impacts generally occur on the edges of larger potential habitat polygons, with the habitat surrounded by rural residential development and farmland. The extent of cleared land in the area means that impacts are unlikely to increase edge effects to retained habitat areas or further reduce their viability. It is generally considered unlikely that potential habitat in this area contributes to the ongoing survival or viability of the species more broadly.

Indirect impacts

Potential indirect impacts to *M. minutiflora* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(e) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat within GPEC and WSA is unlikely to affect the ecology of any local population of *M. minutiflora* because the potential for the species to occur is low.

10.2.3.1(f) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat within the nominated areas is unlikely to fragment or isolate any local population of *M. minutiflora* because the potential for the species to occur is low.

Surveys of the OSO did not detect *M. minutiflora*, but potential habitat remains either side of the OSO corridor in Wianamatta Regional Park. This mapped potential habitat will be fragmented by the OSO. However, the low likelihood of occurrence of *M. minutiflora* in the area considerably reduces the risk of these impacts.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Potential habitat for *M. minutiflora* within GPEC and WSA occurs within the southern extent of the species stronghold in the Castlereagh and Londonderry areas.

There is one known population within GPEC on the edge of Wianamatta Regional Park near Ropes Crossing. This population is disjunct from the majority of known records which occur approximately 7 km to the north-west and are generally associated with larger, more intact remnants of native vegetation and will not be directly or indirectly impacted by development. This population is generally within the southern geographic extent of the species range, although there are two relatively recent (2014) records of the species further south near Mulgoa.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile for *M. minutiflora* (OEH, 2019i) identifies a range of threats to the species. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Habitat degradation

The greatest risk areas for these relevant threats are:

- Within the alignment of the M7/Ropes Crossing Link Road in northern GPEC
- Within Wianamatta Regional Park, where the OSO corridor fragments potential habitat
- At Orchard Hills, where urban development fragments potential habitat

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for *M. minutiflora* are discussed below for each identified indirect impact.

INAPPROPRIATE FIRE REGIMES

The response of *M. minutiflora* to fire is unknown. However, altered fire regimes are an identified threat (OEH, 2019i) and a 2016 fire in the Wianamatta Nature Reserve (outside of the nominated areas to the north of GPEC) may have substantially affected the species. Increased human activity within the nominated areas increases the risk of fire to habitat areas supporting the species.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for *M. minutiflora* being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is

managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk

- Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *M. minutiflora*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

WEED INVASION

M. minutiflora is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban and transport development within GPEC has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

M. minutiflora is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include population 108 that occurs within GPEC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 15) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *M. minutiflora*:
  - Preparation of a Weed Control Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
- Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement weed control measures, including:
  - Submitting a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
  - Undertaking subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
  - Managing and eradicating Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Introduction of a new SEPP (Strategic Conservation Planning) that will set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to the spread of weeds

HABITAT DEGRADATION

Habitat degradation through unrestricted public access and rubbish dumping have been identified as a key threat to *M. minutiflora* (OEH, 2019i). Development within GPEC may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

The Plan further incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high

biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values

- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 2,036.4 ha of potential habitat mapped within protected areas within the area covered by the Plan. This includes potential habitat within:

- Castlereagh Nature Reserve
- Wianamatta Regional Park
- Wianamatta Nature Reserve
- Agnes Banks Nature Reserve
- Windsor Downs Nature Reserve

Four populations occur on public land managed for conservation. They are:

- Castlereagh Nature Reserve – two populations
- Wianamatta Regional Park – one population
- Wianamatta Nature Reserve – one population
- Agnes Banks Nature Reserve – one population

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments and actions that will contribute to the recovery of *M. minutiflora* in the Cumberland subregion. The key commitments and actions relevant to the species are:

- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for *M. minutiflora* in the SCA, as there is approximately 3,518.4 ha of mapped potential habitat in the SCA for this species
- Manage weeds in strategic locations in the Cumberland subregion (Commitment 15) to reduce threats to conservation lands secured within the SCA. This includes preparing a Weed Control Strategy to guide and co-ordinate delivery of a weed control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.13 RAPTORS

This assessment addresses three raptor species together – White-bellied Sea-Eagle (*Haliaeetus leucogaster*), Little Eagle (*Hieraaetus morphnoides*) and Square-tailed Kite (*Lophoictinia isura*).

25.13.1 SPECIES BACKGROUND

LITTLE EAGLE

Little Eagle is a medium-sized bird of prey that occurs throughout the Australian mainland except the most densely forested parts of the Dividing Range escarpment (OEH, 2017i). The species is found throughout NSW, but is more common in the western two-thirds of the state (Saunders and Debus, 2018a).

The species inhabits open eucalypt forest, woodland or open woodland. It also occurs in Sheoak or Acacia woodlands and riparian woodlands of interior NSW (OEH, 2017i).

Little Eagle generally nests in tall living eucalypts (between 5 and 30 m) in open forest, woodland, and remnant woodland within farmland. Nests are generally between 13 and 20 m above ground. They prefer to nest in dense woodland adjacent to open habitat (e.g. grassy woodland) for foraging. Nests are typically:

- In an emergent eucalypt, the tallest in the stand and often with the largest girth
- In woodland patches at least 4.8 ha in size (average 85 ha)
- Mostly within 200 m of the edge of habitat
- More distant from sealed roads (average 838 m) than gravel roads (average 546 m) than tracks (average 304 m)
- At least 38 m from the nearest dwelling (average 457 m)
- At least 1 km from urban development (Saunders and Debus, 2018a)

Little Eagle will forage up to 3 km from the nest, which gives a maximum breeding/foraging territory of 2,800 hectares. Banding data suggest that birds occupy a home range for at least 6-10 years (Saunders and Debus, 2018a).

The species occurs as a single population throughout NSW (OEH, 2017i).

SQUARE-TAILED KITE

Square-tailed Kite is a reddish, medium-sized raptor that occurs along coastal and subcoastal areas from south-western to northern Australia, NSW, Queensland, and Victoria. There are scattered records across NSW (OEH, 2017k).

The species inhabits a variety of forests, including dry woodlands and open forests (OEH, 2017k). Square-tailed Kite prefers timbered watercourses through open or cleared land and the margins between open and timbered country, and can tolerant human disturbance and urban bushland (Saunders and Debus, 2018b).

Nests are generally located along or near watercourses and on the edge of habitat areas, in a fork or on horizontal limbs of a large living trees, and mostly between 15 and 28 m above ground (Saunders and Debus, 2018b).

The species appears to be monogamous as breeding pairs, as they are intolerant of other adults within their breeding territory, and they occupy the same nest site for many years (Saunders and Debus, 2018b).

The species migrates in the summer to south-east NSW to breed, arriving in September and leaving by March (OEH, 2017k). In the Cumberland subregion, breeding has been recorded from July to February (Saunders and Debus, 2018b).

The species occupies large hunting ranges of more than 100 km^2.

WHITE-BELLIED SEA-EAGLE

The White-bellied Sea-Eagle is a large eagle that has long, broad wings and a short, wedge-shaped tail that occurs around the Australian coastline and inland along rivers and wetlands of the Murray Darling Basin. In NSW, it is widespread along the east coast, and along all major inland rivers and waterways (OEH, 2017l).

The species occurs in a variety of habitats, including coastal dunes, tidal flats, grassland, heathland, woodland, and forest close to large bodies of open water including larger rivers, swamps, lakes, and the ocean (OEH, 2017l).

Breeding habitat is constrained to living or dead mature trees within forests or tall woodland within 1 km of rivers, lakes, large dams or creeks, wetlands, and coastlines. Nest are generally located in large emergent eucalypts, often with emergent dead branches or large dead trees nearby, which are used as 'guard roosts' (OEH, 2017l).

25.13.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

The raptors are being assessed as candidate species credit species in terms of breeding habitat for all nominated areas.

The raptors have been identified as potential SAII entities in accordance with the requirement of section 10.2.1.4 of the BAM because of the potential for the development to impact breeding habitat that cannot readily be created at a stewardship site. This SAII assessment addresses direct and indirect impacts on breeding habitat only.

An expert report was prepared for Little Eagle and Square-tailed Kite. Potential breeding habitat for the raptors was mapped on the basis of the expert reports, as well as a KBM, as follows:

- Little Eagle:
  - An expert report for Wilton and GMAC (Saunders and Debus, 2018a) and addendum letter (Saunders, 2020)
  - A KBM for WSA and GPEC
- Square-tailed Kite:
  - An expert report for Wilton and GMAC (Saunders and Debus, 2018b) and addendum letter (Saunders, 2020)
  - A KBM for WSA and GPEC
- White-bellied Sea-Eagle: A KBM for all four nominated areas

The expert reports involved:

- Targeted surveys within the most likely areas of potential breeding and foraging habitat for these species
- Identification of potential breeding and foraging habitat within the nominated areas
- Targeted surveys in potential habitat by the expert as part of preparing the expert report as well as Biosis as part of other targeted surveys for this project (the Biosis surveys were taken into account in preparing the expert report)

The addendum refined the mapping of potential breeding and foraging habitat and clarified the location of such habitat.

25.13.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of the raptors in relation to the subject land is shown in Map 25-11.

RECORDS

Little Eagle

The majority of records of the Little Eagle within the Cumberland subregion are recorded on the Cumberland Plain. This includes 35 records within the nominated areas, or within 5 km of the nominated area boundaries.

Most records are associated with large patches of open woodland that occur within open grassland areas. Some records are found close to the edges of forests along watercourses. A few records were from woodlands associated with wetlands. The records support the conclusion that a mosaic of open woodland and open grassland with scattered trees provides important foraging habitat for the Little Eagle (Saunders and Debus, 2018a).

The expert report concluded that there is a very high likelihood that Little Eagle occurs in the nominated areas at any time of the year and that the nominated areas provide good foraging habitat for the species. There are likely to be 4 to 6 resident pairs resident in Wilton and GMAC, including (Saunders and Debus, 2018a):

- 1 pair in the northern part of GMAC
- 2 pairs in the middle part of GMAC
- 1 pair in the southern part of GMAC
- 1 pair in Wilton

Square-tailed Kite

Square-tailed Kite was seldom recorded in the Cumberland subregion prior to 1990, but the number of records has increased over the last two decades. All records for the Liverpool, Campbelltown and Wollondilly Local Government Areas are more recent than 2000. There are breeding records within the subregion, from near Asquith in 2012, Lane Cove National Park in 2015, and more recently near Penrith, Asquith and South Turramurra (Saunders and Debus, 2018b).

There are 32 records in the nominated areas, including 12 within Wilton and the southern part of GMAC. Another 15 records occur within 5 km of the nominated areas, with 11 occurring just outside the northern part of GMAC. The majority of records are from January to April, which represents the post-breeding dispersal phase (Saunders and Debus, 2018b).

The expert report concluded that there is a very high likelihood that Square-tailed Kite occurs in the nominated areas during the breeding season, and that the nominated areas provide good foraging habitat for the species. There are likely to be 2 to 3 breeding pairs of Square-tailed Kite resident in Wilton and GMAC, including:

- 1 pair centred along the Georges River along the eastern edge of the northern part of GMAC
- 1 pair in the Appin Road area that extends into contiguous forest to the east of the southern part of GMAC
- Possibly 1 pair in the southern part of Wilton

White-bellied Sea-Eagle

There are many records of the White-bellied Sea-Eagle in the Cumberland subregion, although the majority in the Sydney Basin bioregion occur to the east of the subregion along the coast, to the north and south of Sydney.

There are several records of the species in the nominated areas. There is one old record in GPEC and two records in the central part of WSA, including a recent (2017) record. There is a cluster of relatively recent records (2013) within or just outside the central part of GPEC, and several other records in the southern part of GPEC. There are several recent (2018) records just outside the northern part of the GPEC to the east. There are no records in Wilton.

POTENTIAL BREEDING HABITAT

Potential breeding habitat for the raptors has been mapped in all nominated areas.

Potential breeding habitat for Little Eagle and Square-tailed Kite occurs in the urban capable lands of GPEC, GMAC and WSA, and for White-bellied Sea-Eagle, occurs in the urban capable lands of all nominated areas.

Little Eagle

No nests have been recorded in the nominated areas and no evidence of breeding was observed during surveys by ecological consultants or by the authors of the expert report. As the Little Eagle is considered to be resident for at least several consecutive years while nesting, it is likely that if nesting has occurred within the nominated areas it would have been detected. However, suitable nesting habitat is still considered to occur within the nominated areas (Saunders and Debus, 2018a). This view is supported by the occurrence of species records within and around the nominated areas in the breeding season (e.g. a mating pair was observed by Starr et al. (2004) near Camden (Saunders and Debus, 2018a)).

Square-tailed Kite

There is a very high likelihood that Square-tailed Kite occurs within the nominated areas during the breeding season. However, no nests have been recorded in the nominated areas. Breeding was not observed during surveys by the ecological consultants or by the authors of the expert report. As other bird species build similar stick nests it is difficult to identify a Square-tailed Kite nest without the bird being in attendance, which would be required to confirm breeding habitat. The breeding habitat areas indicated in the expert reports (Saunders and Debus, 2018b) are based on the minimum criteria presented in Tables 1 and 2 of the report.

Note that the conclusions in the expert reports are supported by mapping showing 'Breeding and foraging habitat' for Little Eagle and Square-tailed Kite. This habitat is generally restricted to areas outside urban capable lands. Further clarification was sought from the experts and additional refinement of the mapping was completed in June 2020 (Saunders, 2020). The refined mapping was used to define breeding habitat for the species in GMAC and Wilton and calculate impacts consistent with the BAM. KBM mapping was used to identify potential breeding habitat in GPEC and WSA.

25.13.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including the raptors, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

Little Eagle

The baseline mapping for this assessment has mapped 2,935.5 ha of potential breeding habitat for Little Eagle within the nominated areas (not including excluded lands). Approximately 2,907.3 ha (99 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,237.5 ha was avoided for biodiversity purposes
- 669.8 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-35.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-35 shows the amounts of habitat within excluded lands for context only.

Table 25-35: Avoidance outcomes for Little Eagle

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	4,090.7	1,155.2	2,935.5	28.2	2,237.5	669.8	2,907.3

Square-tailed Kite

The baseline mapping for this assessment has mapped 2,919.2 ha of potential breeding habitat for Square-tailed Kite within the nominated areas (not including excluded lands). Approximately 2,874.6 ha (98.5 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,220.2 ha was avoided for biodiversity purposes
- 654.4 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-36.

Table 25-36: Avoidance outcomes for Square-tailed Kite

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	4,198.7	1,279.5	2,919.2	44.6	2,220.2	654.4	2,874.6

White-bellied Sea-Eagle

The baseline mapping for this assessment has mapped 2,432.9 ha of potential breeding habitat for White-bellied Sea-Eagle within the nominated areas (not including excluded lands). Approximately 1,598.9 ha (98.9 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,031.8 ha was avoided for biodiversity purposes
- 567.2 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-37.

Table 25-37: Avoidance outcomes for White-bellied Sea-Eagle in all four nominated areas

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	2,432.9	816.3	1,616.6	17.7	1,031.8	567.2	1,598.9

Avoidance of indirect impacts

Potential indirect impacts to the raptors due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(b) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Little Eagle and Square-tailed Kite

There are likely to be 4 to 6 resident pairs of Little Eagle, and 2 to 3 breeding pairs of Square-tailed Kite (that will use the areas for foraging during the breeding season), in Wilton and GMAC.

The expert report found no evidence of breeding of Little Eagle of Square-tailed Kite, as defined by the presence of a bird on a nest, or the presence of pairs of birds in potential habitat, in Wilton or GMAC. Refined mapping completed in June 2020 did map areas of potential breeding habitat in both Wilton and GMAC (Saunders, 2020).

It is uncertain whether Little Eagle or Square-Tailed Kite resides in GPEC or WSA, or the number of resident individuals. Potential breeding habitat occurs in these nominated areas, and relatively recent records occur within or in close proximity to the nominated areas. It is considered likely that the species uses the nominated areas at least for foraging.

White-bellied Sea-Eagle

It is uncertain whether White-bellied Sea-Eagle resides in any of the nominated areas, and if it does occur, the number of potential resident individuals. Potential breeding habitat occurs in each of the nominated areas, particularly Wilton and GMAC, and recent records occur in WSA and particularly within or just outside the central part of GPEC. It is considered likely that the species uses the nominated areas at least for foraging.

10.2.3.1(c) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for the raptors.

10.2.3.1(d) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

The direct impacts of the development on the raptors are provided in Table 25-38. The direct impacts are mainly associated with development of urban capable land within GMAC, and the transport corridors within the nominated areas. For all raptors, the impacts mainly occur:

- In small, scattered areas of habitat across GMAC, which typically impacts the edges of larger, connected areas of vegetation, or small fragmented remnants. The largest impacts within GMAC occur in proximity to Appin
- In Wianamatta Regional Park where the OSO intersects an area of habitat, which will fragment this habitat into two patches and lead to the isolation of one of the patches from the remainder of habitat in the regional park
- In the central part of GPEC where the OSO mostly removes habitat associated with riparian corridors

- To the edges of smaller scattered patches of habitat in WSA that are mainly associated with riparian corridors
- In small, scattered areas within Wilton, which typically affect the edges of larger areas of connected habitat associated with riparian corridors

It is important to note that potential foraging habitat was also mapped within GMAC and Wilton for Little Eagle and Square-tailed Kite (Saunders, 2020). The potential foraging habitat is generally represented by grassed paddocks adjacent to mapped potential breeding habitat and is not considered to be breeding habitat requiring credit calculations under the BAM.

Table 25-38: Direct impacts on potential breeding habitat (ha) for raptors

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Little Eagle	4.8	18.9	0.7	0.6	3.3	28.2
Square-tailed Kite	5	25.2	0.9	0.3	13.3	44.6
White-bellied Sea-Eagle	2.5	7.9	0.9	0.3	6.2	17.7

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Direct impacts to potential breeding habitat for the raptors are unlikely to affect life cycle processes or impact the viability of any local populations of raptors because:

- Direct impacts to potential breeding habitat for raptors are very small relative to the amount of potential breeding habitat remaining
- Impacts generally occur to the edges of potential breeding habitat that in most cases remains connected to larger patches of habitat associated with gullies and gorges that run down to the Nepean River or along riparian corridors. This reduces the risk that potential breeding habitat becomes isolated from foraging habitat

The development will lead to some fragmentation of potential breeding habitat. This mainly occurs as follows:

- GPEC:
  - In Wianamatta Regional Park where the OSO will fragment habitat into two patches
  - In the central part of the nominated area where the OSO will reduce the size of some habitat patches
- WSA: Along some riparian corridors where the development will reduce the size of patches to some extent

The impacts of habitat fragmentation for these species are considered minor and are unlikely to affect life cycle processes or impact the viability of local populations, because:

- The areas which may be impacted by fragmentation comprise only a small proportion of the total available habitat within the nominated areas
- The mobile nature of the species means that they are considered unlikely to be substantially adversely impacted by the scale of habitat fragmentation which will occur as a result of development under the Plan
- The majority of habitat for these species, including large and well-connected areas of habitat, has been avoided and will be protected under the Plan, which will help to ensure ongoing habitat connectivity into the future

As a result, it is not considered that the development is likely to significantly fragment or isolate the likely resident pairs of Little Eagle and Square-tailed Kite and any population of White-bellied Sea-Eagle in Wilton and GMAC, or fragment or isolate any populations of these species in the WSA or GPEC.

Indirect impacts

Potential indirect impacts to the raptors due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(e) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential breeding habitat is unlikely to affect the ecology of any local populations of raptors because direct impacts to potential breeding habitat for raptors are very small relative to the amount of habitat remaining, and the risk of impacts of habitat fragmentation to these species are minimal.

10.2.3.1(f) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential breeding habitat is unlikely to fragment or isolate any local populations of raptors because in most cases, impacts mainly occur only to the edges of patches and potential breeding habitat usually remains connected to large areas of habitat or along riparian corridors. Further, the mobile nature of these species reduces their vulnerability to impacts of fragmentation.

10.2.3.1(g) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

There are likely to be 4 to 6 resident pairs of Little Eagle, and 2 to 3 breeding pairs of Square-tailed Kite (that will use the areas for foraging during the breeding season), in Wilton and GMAC. It is uncertain whether White-bellied Sea-Eagle resides in any of the nominated areas, and if it does occur, the number of potential resident individuals.

The importance of these resident pairs to other populations outside the nominated areas is uncertain.

Little Eagle occurs as a single population throughout NSW (OEH, 2017i), while Square-tailed Kite appears to be monogamous as breeding pairs, as they are intolerant of other adults within their breeding territory, and they occupy the same nest site for many years (Saunders and Debus, 2018b).

The expert report found no evidence of breeding of Little Eagle or Square-tailed Kite, as defined by the presence of a bird on a nest, or the presence of pairs of birds in potential habitat, in Wilton or GMAC. If breeding does not occur within the nominated areas, it is likely that these species breed outside the nominated areas and use the nominated areas for foraging.

10.2.3.1(h) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profiles for the three species identify a range of threats. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Non-target poisoning during pest animal control
- Habitat disturbance

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for the species are discussed below for each identified indirect impact.

NON-TARGET POISONING DURING PEST ANIMAL CONTROL

Accidental poisoning during pest animal control is recognised as a threat to the species. Poisoning of pest animals may occur during implementation of the Plan as part of the Pest Animal Control Implementation Strategy (Commitment 16).

To mitigate the risk to the three raptor species, the Plan includes a specific commitment and action to *"Ensure that the Pest Animal Control Implementation Strategy specifies the use of pest control techniques that will reduce the risk of secondary poisoning from Pindone or second-generation rodenticides"* (Commitment 16, Action 3)

This measure is considered adequate to address the threat to the species.

HABITAT DISTURBANCE

Habitat disturbance (particularly to nest sites) is recognised as a threat to the species. Habitat disturbance can occur due to a range of mechanisms including:

- Uncontrolled access to areas of high biodiversity
- Inappropriate land management practices

The Plan incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Retaining large trees (including dead trees) (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction (under Commitment 5)
- Establishing ecological setbacks (500m circular setback from where nests are located in undisturbed bushland or 250m for nests adjacent to existing development) for raptor nests to provide a buffer to adjacent development
- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program
- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

An estimate of the potential breeding habitat for raptors in protected lands in the area covered by the Plan is:

- Little Eagle: 297.8 ha
- Square-tailed Kite: 330 ha
- White-bellied Sea-Eagle: 389.4 ha

Each of the raptors has been recorded within several of the following protected lands within and outside the Cumberland subregion, including:

- Wianamatta Nature Reserve
- Dharawal National Park
- Dharug National Park
- Scheyville National Park
- Cattai National Park
- Yengo National Park
- Blue Mountains National Park
- Dharawal National Park
- Royal National Park
- Castlereagh Nature Reserve
- Windsor Downs Nature Reserve

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of the raptors in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments and actions relevant to the species are:

- Species-specific commitments under Commitment 5 to retain large trees (≥ 50cm DBH) during precinct planning where possible and establish ecological setbacks for raptor nests to provide a buffer to adjacent development
- A specific measure in Appendix E of the Plan to establish ecological setbacks (500m circular setback from where nests are located in undisturbed bushland or 250m for nests adjacent to existing development) for raptor nests to provide a buffer to adjacent development
- Ensuring that the Pest Animal Control Implementation Strategy specifies the use of pest control techniques that will reduce the risk of secondary poisoning from Pindone or second-generation rodenticides (Commitment 16)
- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential breeding habitat for raptors in the SCA, as there is 17,566.5 ha, 17,322.6 ha, and 13,699.7 ha of mapped potential breeding habitat in the SCA for the Little Eagle, Square-tailed Kite and White-bellied Sea Eagle respectively

25.14 PSEUDOPHRYNE AUSTRALIS

25.14.1 SPECIES BACKGROUND

Red-crowned Toadlet (*Pseudophryne australis*) is a small frog that is dark brown to black, with distinctive reddish-orange patches. It is a relatively long-lived species (up to 8 to 10 years) (OEH, 2019j).

The species inhabits periodically wet drainage lines below sandstone ridges within open forests, mostly at the interface of Hawkesbury sandstone and Wianamatta and Narrabeen shale (OEH, 2019j).

The Red-crowned Toadlet appears to be largely restricted to the immediate vicinity of suitable breeding habitat. Breeding habitat comprises dense vegetation and debris beside ephemeral creeks and gutters (OEH, 2019j). The species deposits eggs in terrestrial nests beneath rocks and logs or in leaf litter, and relies on rainfall to wash the partially developed tadpoles into ephemeral creeks for completion of the reproductive cycle (NSW Scientific Committee, 2002).

Outside the breeding period, the species disperses to refuge areas close to breeding sites, under rocks and amongst masses of dense vegetation or thick piles of leaf litter generally on sandstone ridges (OEH, 2019j).

The Red-crowned Toadlet has a restricted distribution. It is confined to the Sydney Basin, from Pokolbin in the north, the Nowra area to the south, and west to Mt Victoria in the Blue Mountains (OEH, 2019j).

Records for the species are widespread surrounding the Cumberland subregion, but few records occur in the subregion.

25.14.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

The Red-crowned Toadlet is being assessed as a candidate species credit species for GPEC, GMAC, and Wilton.

The species has been identified as a potential SAII entity in accordance with the requirement of section 10.2.1.4 of the BAM because of its very high susceptibility to the disease chytrid fungus, which triggers Principle 4 of the BC Regulation.

25.14.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of Red-crowned Toadlet in relation to the subject land is shown in Map 25-12.

There are no records for the Red-crowned Toadlet within the nominated areas. The closest records occur within a few kilometres of GPEC, GMAC, and Wilton.

Approximately 1,082 hectares of potential habitat for Red-crowned Toadlet has been identified within the nominated areas. This occurs in Wilton and GMAC. No potential habitat was mapped within GPEC and WSA.

Potential habitat in Wilton and GMAC generally occurs in scattered patches within the vicinity of gorges and gullies that occur mainly around the edges of the nominated areas. The vast majority of potential habitat in GMAC is restricted to the southern part of the nominated area, with only one small patch of habitat occurring in the northern part.

25.14.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including Red-crowned Toadlet, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

No known populations of Red-crowned Toadlet occur within GMAC and Wilton. Avoidance of impacts to populations was therefore not a relevant consideration for this species.

The baseline mapping for this assessment has mapped 869 ha of potential habitat for Red-crowned Toadlet within the nominated areas (not including excluded lands). Approximately 859.7 ha (98.9 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 645.1 ha was avoided for biodiversity purposes
- 214.6 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-39.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-39 shows the amounts of habitat within excluded lands for context only.

Table 25-39: Avoidance outcomes for Red-crowned Toadlet

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	1,082	213	869	9.3	645.1	214.6	859.7

Avoidance of indirect impacts

Potential indirect impacts to Red-crowned Toadlet due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within GMAC and Wilton will not directly impact any known populations of Red-crowned Toadlet.

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for Red-crowned Toadlet.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 9.3 ha of potential habitat for Red-crowned Toadlet will be directly impacted by the development. This is 1.1 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development

are associated with urban development. The direct impacts mainly occur at the very edges of potential habitat associated with gorges and gullies that run down to the Nepean River, in the following locations:

- Scattered areas of Wilton
- Southern part of GMAC

The direct impacts of the development on Red-crowned Toadlet are provided in Table 25-40.

Table 25-40: Direct impacts on Red-crowned Toadlet

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	2.3	7	0	0	0	9.3

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

The impacts to the areas of potential habitat within Wilton and GMAC are unlikely to impact the ongoing survival or viability of the Red-crowned Toadlet in the local area because:

- Only a very small proportion (1.1 per cent) of this potential habitat is directly impacted. The vast majority of potential habitat has been avoided for biodiversity or other purposes
- There are no records or known populations of the species in the area. While many records of the species occur surrounding the Cumberland subregion, the species is generally not known from the subregion
- The impacts are unlikely to cause fragmentation or isolation of habitat because, where impacts occur, only the edges of potential habitat at the tops of gorges and gullies are impacted
- The corridors of potential habitat that exist along gorges and gullies are maintained

Indirect impacts

Potential indirect impacts to Red-crowned Toadlet due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat within Wilton and GMAC is unlikely to affect the ecology of any local population of Red-crowned Toadlet because:

- Only a very small proportion (1.1 per cent) of this potential habitat is directly impacted
- There are no records or known populations of the species in the locality and the species is generally not known from the subregion, reducing the risk that breeding habitat occurs in the locality

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat within Wilton and GMAC is unlikely to fragment and isolate any local population because impacts occur only to the very edges of potential habitat and the corridors of potential habitat that exist along gorges and gullies are maintained.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Development within Wilton and GMAC will not directly impact any records or known populations of Red-crowned Toadlet. No populations are known from these nominated areas.

Potential habitat within Wilton and GMAC is not at the limit of the species range. Records for the species are widespread surrounding the Cumberland subregion.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile for the Red-crowned Toadlet identifies a range of threats to the species (OEH, 2019j). Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Reduction in water quality
- Inappropriate fire regimes
- Habitat disturbance including collection of bush rock and recreational activities
- Infection with amphibian chytrid fungus

The greatest risk areas for these relevant threats are at the edges of potential habitat associated with gorges and gullies that run down to the Nepean River in the northern part of Wilton, and the western part of GMAC.

The Plan includes commitments to mitigate indirect impacts from urban and industrial development, infrastructure, and intensive plant agriculture (Commitment 5) and from major transport corridors (Commitment 6) on TECs and species and their habitat, including meeting specific mitigation requirements in accordance with Appendix E of the Plan. Relevant actions under these commitments and specific mitigation measures for the Red-crowned Toadlet are discussed below for each identified indirect impact.

REDUCTION IN WATER QUALITY

A reduction in water quality and changes to hydrology are recognised as a principal threat to the species (OEH, 2019j). Key issues relate to increased pollutants in runoff from developed areas.

The Plan incorporates a range of general measures to mitigate the risks associated with changes to hydrology. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area that will require proponents undertaking development to implement measures to manage hydrological impacts, including in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage, and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures for major transport corridors based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines (NSW RTA and NGH Environmental Consultancy, 2011). These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to habitat for the species
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

INAPPROPRIATE FIRE REGIMES

High frequency fire is identified as a potential threat to the Red-crowned Toadlet (OEH, 2019j).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 17) to manage fire in strategic locations in the Cumberland subregion. This includes a number of actions with the most relevant to the outcome for the Red-crowned Toadlet being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy in priority locations that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Introduction of a new SEPP (Strategic Conservation Planning) that will:
    - Set out development controls to avoid and minimise impacts of future development on biodiversity values in avoided land and the SCA. The SEPP requires the consent authority to be satisfied that the development is managed to avoid adverse impacts to biodiversity values prior to granting approval. This would include consideration of risks to biodiversity values relating to managing fire risk
    - Require asset protection zones (APZs) to be wholly within urban capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the Red-crowned Toadlet. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

HABITAT DISTURBANCE INCLUDING COLLECTION OF BUSH ROCK AND RECREATIONAL ACTIVITIES

Inappropriate habitat disturbance has been identified as a threat to the Red-crowned Toadlet (OEH, 2019j).

The Plan further incorporates a range of general measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- Incorporation of development controls into DCPs for each nominated area to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 26) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program

- A commitment (Commitment 20) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the Red-crowned Toadlet from inappropriate habitat disturbance as a result of development. This is because:

- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

INFECTION WITH AMPHIBIAN CHYTRID FUNGUS

Amphibian chytrid fungus, which causes the infection known as chytridiomycosis, is recognised as a threat to the Red-crowned Toadlet (OEH, 2019j).

Chytrid fungus is already present in the Cumberland subregion, although there may be pockets of disease free areas that are inhospitable to the growth of the disease (for example, due to salinity levels or elevated concentrations of trace metals).

The Plan incorporates a range of measures to manage the risks associated with the spread of infection/disease. In summary, these include:

- A commitment (Commitment 18) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
    - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion (this measure specifically relates to chytrid fungus)
    - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures to protect the environment during construction, including best practice site hygiene protocols to minimise the spread of disease

The package of measures in the Plan is expected to adequately manage the risk to potential habitat from diseases, pathogens, and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 24.9 ha of potential habitat for the Red-crowned Toadlet mapped within protected areas in the area covered by the Plan. This comprises potential habitat within the Upper Nepean State Conservation Area.

Populations are known from many reserves managed for conservation outside the Cumberland subregion, including:

- Nattai National Park
- Blue Mountains National Park
- Wollemi National Park
- Dharawal National Park
- Royal National Park
- Berowra Valley National Park

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of Red-crowned Toadlet in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments and actions relevant to the species are:

- Secure a minimum of 5,325 ha of native vegetation in conservation lands within the SCA (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for Red-crowned Toadlet in the SCA, as there is approximately 8,400.4 ha of mapped potential habitat in the SCA for this species
- Support new or existing programs to control key diseases affecting TECs and species in the Cumberland subregion (Commitment 18)
- Manage fire in strategic locations in the Cumberland subregion (Commitment 17) to support the maintenance of biodiversity values on land secured within the SCA. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

26 Impact summary

The BCAR must include the number and classes of biodiversity credits that would be required to be retired if the offset rules under the BC Act applied (clause 6.9(c) BC Regulation).

This Chapter identifies:

- Impacts on native vegetation (PCTs) and species requiring offsets and the native vegetation not requiring offsets
- Areas not requiring assessment in accordance with section 10 of the BAM
- Biodiversity credits that would be required to be retired if the offset rules under the BC Act applied

It is important to note that the number and classes of biodiversity credits needed to offset the impacts of the development are not required to be retired under a strategic biodiversity certification (see Part 1). However, the NSW Environment Minister must be satisfied that the 'approved conservation measures' under the Plan adequately address the likely impacts on biodiversity values. The Minister will have regard to the BCAR in making this decision.

The Plan has had regard to the credit output of the BAM in determining the commitments under the conservation program. The adequacy of the commitments in offsetting the impacts of the development are evaluated in Part 7.

26.1 IMPACTS REQUIRING OFFSETS

Table 26-1 and Table 26-3 identify the impacts on native vegetation and species that require offsets.

Map 26-1 and Map 26-2 provide maps of impacts on native vegetation and species that require offsets and impacts on native vegetation and species that do not require offsets.

26.1.1 NATIVE VEGETATION REQUIRING OFFSETS

Section 10.3.1 of the BAM specifies that an offset is required for impacts on native vegetation where the vegetation integrity score is:

- ≥15 where the PCT is representative of an endangered or critically endangered ecological community
- ≥17 where the PCT is associated with threatened species habitat (as represented by ecosystem credits), or is representative of a vulnerable ecological community
- ≥20 where the PCT is not representative of a TEC or associated with threatened species habitat

The PCTs/vegetation zones requiring offsets are provided in Table 26-1.

The PCT/vegetation zones not requiring offsets are provided in Table 26-2.

Table 26-1: PCTs/vegetation zones requiring offsets

PCT	Condition
724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
725 - Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
781 - Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Thinned
830 - Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Intact

PCT	Condition
	Thinned
835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Intact

PCT	Condition
835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland
849 - Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland
850 - Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland
1395 - Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland

26.1.2 SPECIES REQUIRING OFFSETS

The species credit species requiring offsets are provided in Table 26-3.

Table 26-3: Species credit species requiring offsets

Species	Common Name
Acacia bynoeana	Bynoe's Wattle
Acacia pubescens	Downy Wattle
Allocasuarina glareicola	-
Callocephalon fimbriatum	Gang-gang Cockatoo
Calyptorhynchus lathami	Glossy Black Cockatoo
Cercartetus nanus	Eastern Pygmy-possum
Chalinolobus dwyeri	Large-eared Pied Bat
Dillwynia tenuifolia	-
Epacris purpurascens var. *purpurascens*	-
Grevillea juniperina subsp. *juniperina*	-
Grevillea parviflora subsp. *parviflora*	Small-flower Grevillea
Haliaeetus leucogaster	White-bellied Sea-Eagle
Heleioporus australiacus	Giant Burrowing Frog
Hibbertia fumana	-
Hibbertia puberula	-
Hieraaetus morphnoides	Little Eagle
Lathamus discolor	Swift Parrot
Litoria aurea	Green and Golden Bell Frog
Lophoictinia isura	Square-tailed Kite
Marsdenia viridiflora subsp. *viridiflora* - endangered population	*Marsdenia viridiflora* R. Br. subsp. *viridiflora* population in the Bankstown, Blacktown, Camden, Campbelltown, Fairfield, Holroyd, Liverpool and Penrith local government areas
Maundia triglochinoides	-
Melaleuca deanei	Deane's Paperbark
Meridolum corneovirens	Cumberland Plain Land Snail
Micromyrtus minutiflora	*Micromyrtus minutiflora*
Myotis macropus	Southern Myotis
Ninox strenua	Powerful Owl
Persicaria elatior	Tall Knotweed
Persoonia bargoensis	Bargo Geebung
Persoonia nutans	Nodding Geebung
Petaurus norfolcensis	Squirrel Glider

Species	Common Name
Phascolarctos cinereus	Koala
Pimelea curviflora var. *curviflora*	-
Pimelea spicata	Spiked Rice-flower
Pomaderris brunnea	Brown Pomaderris
Pseudophryne australis	Red-crowned Toadlet
Pterostylis saxicola	Sydney Plains Greenhood
Pultenaea parviflora	-
Pultenaea pedunculata	Matted Bush-pea
Tyto novaehollandiae	Masked Owl

26.1.3 PRESCRIBED IMPACTS REQUIRING OFFSETS

The BAM does not calculate biodiversity credits to offset prescribed impacts, and additional offsets may be proposed should mitigation measures or adaptative management not be considered adequate to avoid prescribed impacts.

Relevant prescribed impacts are assessed in detail in Chapter 24, including the mitigation measures proposed to address these impacts. The commitments and mitigation measures in the Plan are expected to adequately avoid and mitigate prescribed impacts and no additional offsets for prescribed impacts are considered necessary. A summary of the justification for not requiring offsets for each prescribed impact is provided in Table 26-4.

Table 26-4: The need for offsets for prescribed impacts

Prescribed impact type	Potential direct impacts	Potential indirect impacts	Requirement for offsets	Justification
Karst, caves, crevices, cliffs	Removal or destruction (e.g. cracking or collapse) of habitat	Recreational use/ disturbance Noise or light disturbance	No	Impacts unlikely to occur
Rocks	Removal of habitat (rocks)		No	Impacts unlikely to occur
Human-made structures	Removal of habitat (structures)	Human disturbance Noise or light disturbance	**Microbats** No **Green and Golden Bell Frog** No	**Microbats** The Plan includes mitigation measures to address risks to microbat species associated with impacts to human-made structures, including preconstruction surveys and artificial breeding and roosting habitat. These mitigation measures are considered adequate to compensate for the loss of roosting and potential breeding habitat. This type of habitat loss will be a long-term process and commensurate roosting opportunities will remain available to microbat populations **Green and Golden Bell Frog** Impacts are unlikely to occur to this species– impacted human made structures supporting potential habitat for the species only represent low quality potential movement corridors through suburbia
Non-native vegetation	Removal of habitat (non-native vegetation)	Recreational use/disturbance Weed invasion Spread of plant/animal disease Pest animals/predation/ competition Soil erosion/sedimentation Urban run-off (water quality)	**Native flora** No **Native fauna** No	**Native flora** Impacts to flora species associated with non-native vegetation are largely a result of GIS mapping inconsistencies between expert species polygons and native vegetation mapping prepared for this project, which have resulted in many small 'slivers' of mapped habitat over-lapping into non-native vegetation polygons One area of habitat associated with non-native vegetation for *Hibbertia fumana* and *Hibbertia puberula,* comprising a total of 1.05 hectares, occurs in a materials storage yard and has undergone complete clearance and soil re-profiling and does not support habitat for either species. The remainder of non-native vegetation impacts occur as small sliver polygons ≤0.01 ha in area Impacts to *Pimelea spicata* are also mostly associated with small slivers created from differences in GIS mapping methods with 274 of the 287 impacted polygons being ≤0.1 ha in area. The remaining larger areas of mapped habitat

Prescribed impact type	Potential direct impacts	Potential indirect impacts	Requirement for offsets	Justification
				are associated with areas of dense African Olive infestations in the Menangle area, and areas of highly disturbed vegetation generally showing signs of soil compaction, including residential yards and dwellings (buildings) None of the impacts to *Hibbertia fumana, Hibbertia puberula* or *Pimelea spicata* associated with non-native vegetation are considered to need additional offsets due to the very low condition of the potential habitat impacted **Native fauna** Level of direct and indirect impacts to Grey-headed Flying-fox, microbats, native birds, Spotted-tail Quoll and Green and Golden Bell Frog associated with the removal of habitat represented by non-native vegetation is minor in nature. This is due to exotic vegetation representing only a fraction of the total impacted habitat for each species and generally being of only marginal habitat value for most of these species. Furthermore, the level of impact is also minor when compared to the amount of non-native vegetation habitat and higher quality native vegetation habitat that will be avoided or not impacted by the development within the Plan area. Significant offsets will be secured as a result of impacts to native vegetation and associated habitats
Habitat connectivity/ movement	N/A	Reduction in habitat connectivity	No	Most key areas of habitat connectivity within the nominated areas have been avoided and will not be impacted The Plan includes a range of commitments and mitigation measures to address potential impacts on habitat connectivity, including for Koala. These measures are considered adequate to address these impacts
Water bodies/ hydrological processes	Removal of habitat (water bodies)	Change in water flows/quantity Urban run-off (water quality)	**Species associated with waterbodies (except Green and Golden Bell Frog)** No **Species associated with waterbodies - Green and Golden Bell Frog**	**Species associated with waterbodies (except Green and Golden Bell Frog)** Waterbodies directly impacted by the development provide only marginal forage habitat to Southern Myotis and water birds, with higher order streams and larger wetlands/waterbodies avoided. Only very small amounts of potential habitat for White-bellied Sea Eagle containing water bodies are being impacted relative to suitable habitat remaining in the subregion **Species associated with waterbodies - Green and Golden Bell Frog** While the waterbody impacted at St Marys Leagues Club has the potential to provide breeding habitat for any population of Green and Golden Bell Frog

Prescribed impact type	Potential direct impacts	Potential indirect impacts	Requirement for offsets	Justification
			No **Species and TECs potentially affected by hydrological processes** No	that may occur along Ropes Creek, the population was not recorded during recent targeted surveys (see Supporting Document I) **Species and TECs potentially affected by hydrological processes** The Plan includes a range of general mitigation measures and several commitments or actions to address potential impacts to species and TECs associated with changes to hydrological processes. These measures are considered adequate to address these impacts
Vehicle strikes	Death of species individuals	N/A	No	The likelihood of vehicle strike is considered low for most species. The Plan includes a range of commitments and mitigation measures to address potential impacts associated with vehicle strikes on Koala and commitments to avoid and minimise impacts to areas of habitat connectivity during transport corridor design relevant to other species. These measures are considered adequate to address these potential impacts

26.2 IMPACTS NOT REQUIRING FURTHER ASSESSMENT

Areas that do not require assessment in accordance with section 10. 4 of the BAM include:

- Urban native/exotic vegetation
- Non-offsettable grassland
- Cleared land and existing building

26.3 BIODIVERSITY CREDIT CALCULATIONS

The biodiversity credit reports are provided at Supporting Document E.

26.3.1 ECOSYSTEM CREDITS

Table 26-5 to Table 26-8 identify the area of impact and associated number of biodiversity credits for each impacted PCT within each nominated area that would be required to be retired if the offset rules applied under the BC Act.

The total number of ecosystem credits that would be required to be retired to offset the impact of the proposed development on PCTs is 40,082 credits.

As noted, the number and classes of biodiversity credits needed to offset the impacts of the development are not required to be retired under a strategic biodiversity certification (see Part 1). The adequacy of the commitments in offsetting the impacts of the development are evaluated in Part 7.

Table 26-5: Ecosystem credits - Wilton

Vegetation zone	Vegetation integrity loss	Area (ha)	Ecosystem credits
849_Intact	53.9	1.6	53
849_Thinned	42.3	23.4	617
849_Scattered_trees	18.3	23.8	271
849_DNG	24.1	148.7	2,237
850_Scattered_trees	38.1	0.9	22
850_DNG	25.7	159.6	2,559
1395_Intact	72.9	11.0	499
1395_Thinned	63.9	70.8	2,830
1395_Scattered_trees	30.0	17.9	336
1395_DNG	28.4	171.2	3,033
	Total	**628.8**	**12,457**

Table 26-6: Ecosystem credits - GMAC

Vegetation zone name	Vegetation integrity loss	Area (ha)	Ecosystem credits
830_Intact	48.3	0.04	1
830_Thinned	20.1	0.01	1
835_Intact	76.6	1.3	49
835_Thinned	57.1	7.2	207
835_Scattered_trees	68.7	0.2	6
849_Intact	53.9	10.8	362

26.3.2 SPECIES CREDITS

Table 26-9 to Table 26-12 identifies the area of impact and associated number of biodiversity credits for each impacted species credit species within each nominated area that would be required to be retired if the offset rules applied under the BC Act.

The total number of species credits that would be required to be retired to offset the impact of the proposed development on species credit species is 164,103 credits.

METHOD FOR CALCULATING SPECIES CREDITS FOR EPACRIS PURPURASCENS VAR. PURPURASCENS

Epacris purpurascens var. *purpurascens* is identified under the BAM as a species where the unit of measure used to calculate credits is a count of individuals rather than area of habitat.

The consulting team developed a method to address this requirement. The method uses BioNet records for the species in the locality of the nominated areas to derive an estimate of the number of individuals per hectare.

The steps involved in the method were:

- All BioNet records of the species that occur within 20kms of modelled habitat were selected to allow for consideration of populations in the locality of the nominated areas. Records used were sourced from "As Held BioNet Data" (at May 2021). A total of 314 records were considered, once duplicates had been removed
- To group individual records into populations, and to provide an estimated area within which the record occurs, each BioNet record was buffered by 56.42 m (radius) to create 1ha buffers surrounding each point
- Buffer areas were then combined (with overlapping areas dissolved) to ascertain an area value for each group of records. A total of 108 buffer areas (populations) were created, ranging in area from 1ha to 6.7 ha

- BioNet records were interrogated to determine the number of individual plants each record represents. Where no counts were provided the number of individuals was assumed to be one. Numbers of individuals per BioNet record ranged from 1 to 25,000. When these were provided as a range, the mid-point of the range was used
- The total individuals present within each buffer area (based on all BioNet records within each buffer area) were then summed to determine the number of individuals per population. The total individuals per population was divided by the total area of the buffer to ascertain the individuals per hectare estimate
- Individuals per hectare values were ranked and the median value of 8 individuals per hectare was selected. The median value is considered to be more suitable than the mean to return the central tendency for a skewed number distribution such as this dataset. The data ranges from 1 individual per hectare to 27,500 individuals per hectare, with 94 of the 108 total entries returning less than 1,000 individuals per hectare

Based on the median value of 8 stems per hectare, the total estimated impacts to *Epacris purpurascens* var. *purpurascens* across the nominated areas 1,044 stems (across 87 hectares of modelled potential habitat).

ACCREDITED ASSESSOR:	N/A
VERSION CONTROL:	
VERSION:	Final This version of the report is the version submitted to regulators in 2021 with the application for biodiversity certification under the BC Act and for endorsement under the EPBC Act. Since then, several changes have been made to the Plan and to species listings under the EPBC Act. These changes are addressed in two addendums to this report.
DATE:	2021

Part 6A Contents

Part 6A List of Figures

Part 6A List of Tables

27 Introduction

Parts 6a and 6b of the Cumberland Plain Assessment Report present the impact assessment for relevant matters protected under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

27.1 SCOPE OF THE EPBC ACT ASSESSMENT

As outlined in Chapter 1, the scope of the EPBC Act assessment includes:

- Urban and industrial development within urban capable land in nominated areas
- Infrastructure within urban capable land in nominated areas, as well as 'essential' infrastructure in limited cases within avoided lands in the nominated areas
- Intensive plant agriculture within the agribusiness precinct in the Western Sydney Aerotropolis (WSA)
- Western Sydney Major Infrastructure Corridors (transport corridors) within and outside nominated areas

Chapter 7 in Part 2 of the report provides details about these development types and locations.

27.2 STRUCTURE AND APPROACH TO PARTS 6A AND 6B

Part 6a (this document) includes:

- Chapter 27: Introduction (this chapter)
- Chapter 28: Description of the protected matters affected by the Plan
- Chapter 29: Listed threatened flora species
- Chapter 30: Listed threatened fauna species
- Chapter 31: Listed threatened ecological communities

Part 6b includes:

- Chapter 32: Listed migratory species
- Chapter 33: Ramsar wetlands
- Chapter 34: World and National Heritage
- Chapter 35: Areas of Commonwealth land
- Chapter 36: Analysis of the transport program
- Chapter 37: Analysis of the urban and industrial program
- Chapter 38: Cumulative impact assessment

Chapters in these Parts address the Terms of Reference for the assessment as they relate to specific protected matters. Parts 1, 2, 3, 4, and 7 of the report also address components of the Terms of Reference and must be read in conjunction with Parts 6a and 6b for a complete understanding of the project. Section 4.2.2 (in Chapter 4 of Part 1) sets out the Terms of Reference in full and identifies where they have been addressed throughout the report.

Given the size and complexity of the assessment report, each chapter in Parts 6a and 6b attempts to provide a stand-alone analysis of the relevant issues. However, to avoid excessive repetition each chapter includes cross references to other relevant sections of the report and supporting documents where it is appropriate to do so. For example, details about the baseline data used in the assessment are provided in Part 3 of the report.

Each chapter provides:

- An introduction that sets out the assessment approach for those protected matters
- Descriptions of the relevant protected matters
- Analysis of:
    - How impacts have been avoided
    - Any direct impacts and offsets

  - Potential indirect impacts and mitigation measures
  - An evaluation of the outcomes for each protected matter against the relevant requirements of the EPBC Act and Terms of Reference
- Where appropriate, detailed attachments for any specific technical information that is best presented separately and out of the main text
- Maps of the protected matters (e.g. habitat and records for threatened species). In some cases, these are presented within chapters and in others are presented as separate files which can be viewed as layered PDFs. Layered PDFs enable more information to be presented on maps and allow viewers to turn layers on and off as they interrogate the information

Reference lists are provided at the end of both Part 6a and 6b.

28 Description of the protected matters affected by the Plan

This Chapter describes the protected matters likely to be affected by the Plan by:

- Providing a high-level description of the existing environment within the Strategic Assessment Area
- Identifying the relevant matters for assessment under the EPBC Act

28.1 EXISTING ENVIRONMENT

As required by Clause 3.1 of the Terms of Reference:

> *The Report must describe the nature of the environment within the Strategic Assessment Area, and other areas outside the Strategic Assessment Area that may be impacted by actions taken under the Plan. This must include (at a minimum):*
>
> 1. *A description of historical and current land use*
> 2. *The extent and quality of native vegetation present including detailed mapping of ecological communities and habitat for threatened species listed under the EPBC Act*
> 3. *The nature of the environment, including ecosystem processes and threatening processes*
> 4. *A description of the landscape context for key environmental matters, including connectivity, habitat fragmentation and ecological processes*
> 5. *A spatial map of areas that are already protected for environmental purposes, including Bio-banking and Biodiversity Stewardship sites*

This section broadly addresses these requirements. For the Strategic Assessment Area, it provides:

- A discussion of historical and existing land uses
- An overview of native vegetation
- A description of ecological processes
- A description of threatening processes
- Information about currently protected areas

Detailed information about threatened ecological communities (TECs) and species (e.g. mapping of individual species habitat) as well as relevant protected matters that sit outside the Strategic Assessment Area is provided elsewhere in this report.

28.1.1 HISTORICAL AND EXISTING LAND USES

The Strategic Assessment Area occurs primarily within the Cumberland IBRA subregion of Western Sydney (Cumberland subregion). The Cumberland subregion is a broad geographic basin that is bounded by the Hornsby Plateau in the north, the base of the Blue Mountains in the west, the Woronora plateau in the south, and the centre of Sydney to the east. It has an area of approximately 275,000 hectares, rising gradually from the flat low-lying areas at sea level in the east to an altitude of around 350 metres on the margins to the north and south.

The Strategic Assessment Area has been greatly affected by historical and ongoing land use pressures. Its gentle undulating plains and fertile soils mean it has been a focus of agriculture and occupation both before and after European settlement (DECCW, 2011).

Before European settlement it had extensive grassy woodlands and abundant fauna. Hundreds of records of Aboriginal sites have been found across the subregion, suggesting it was an important area for Aboriginal people. Records indicate Aboriginal occupation of the Sydney region for at least 20,000 years, and possibly 40,000 years (Nanson, Young et al., 1987; Stockdon, 2009; Stockton & Holland, 1974). There also is evidence of Aboriginal people using fire to manage the landscape to establish mosaics of forest and grassland in a way that facilitated hunting of kangaroos (Gammage, 2011).

Since European settlement the Strategic Assessment Area has been used for agriculture and more recently for urban development. Agriculture was established by European settlers in 1792, and since the mid-1900s most of the area has been subject to grazing or cultivation (Tozer, 2003). Fire and clearing have been used extensively to support this.

In the second half of 1900s, Sydney's growth accelerated and residential, commercial and industrial areas expanded further into the Cumberland subregion (Benson & Howell, 1990). At 2019, the Cumberland subregion is expected to support 44 per cent of Sydney's population (DECCW, 2011). The need to accommodate and provide services for the increasing urban population has put pressure on existing agriculture. The Sydney Metropolitan Area is predicted to reach 6 million by 2036. (DECCW, 2011). One recent study projected that on the current trajectory, by 2031 total food production in the Basin may reduce by 60 per cent, including 90 per cent of fresh vegetable production (Institute for Sustainable Futures, 2016).

28.1.2 NATIVE VEGETATION

The native vegetation in the Cumberland subregion is diverse and very different to the surrounding areas. It supports a variety of flora and fauna, including a range of migratory and threatened species. As a result of historical and ongoing patterns of use, the Cumberland subregion and its biodiversity have suffered significant disturbance and it is thought to be one of the most threatened regions in NSW (DEC, 2005b). Many of the ecological communities and the fauna and flora they support are listed as threatened under both NSW and Commonwealth environmental legislation. Approximately 8 per cent of the remaining bushland is protected in reserves (DECCW, 2011).

Areas of remaining native vegetation (see Figure 28-1) are often of high conservation value as they may contain the only remaining habitat for ecological communities and species that rely on the Cumberland subregion for survival.

Native vegetation remaining in the Strategic Assessment Area comprises 39 different PCTs which represent 19 vegetation classes within 10 vegetation formations.

In 2010 only 13 per cent of the pre-1750 extent of the region's vegetation remained as intact, with an additional 12 per cent occurring as scattered trees in disturbed areas (DECCW, 2011). What remains is often highly fragmented. An estimated 2,446 individual native vegetation remnants remain, and the 81 largest patches (containing >50 ha) represent 51 per cent of the remaining native vegetation across the Cumberland subregion (DECCW, 2011).

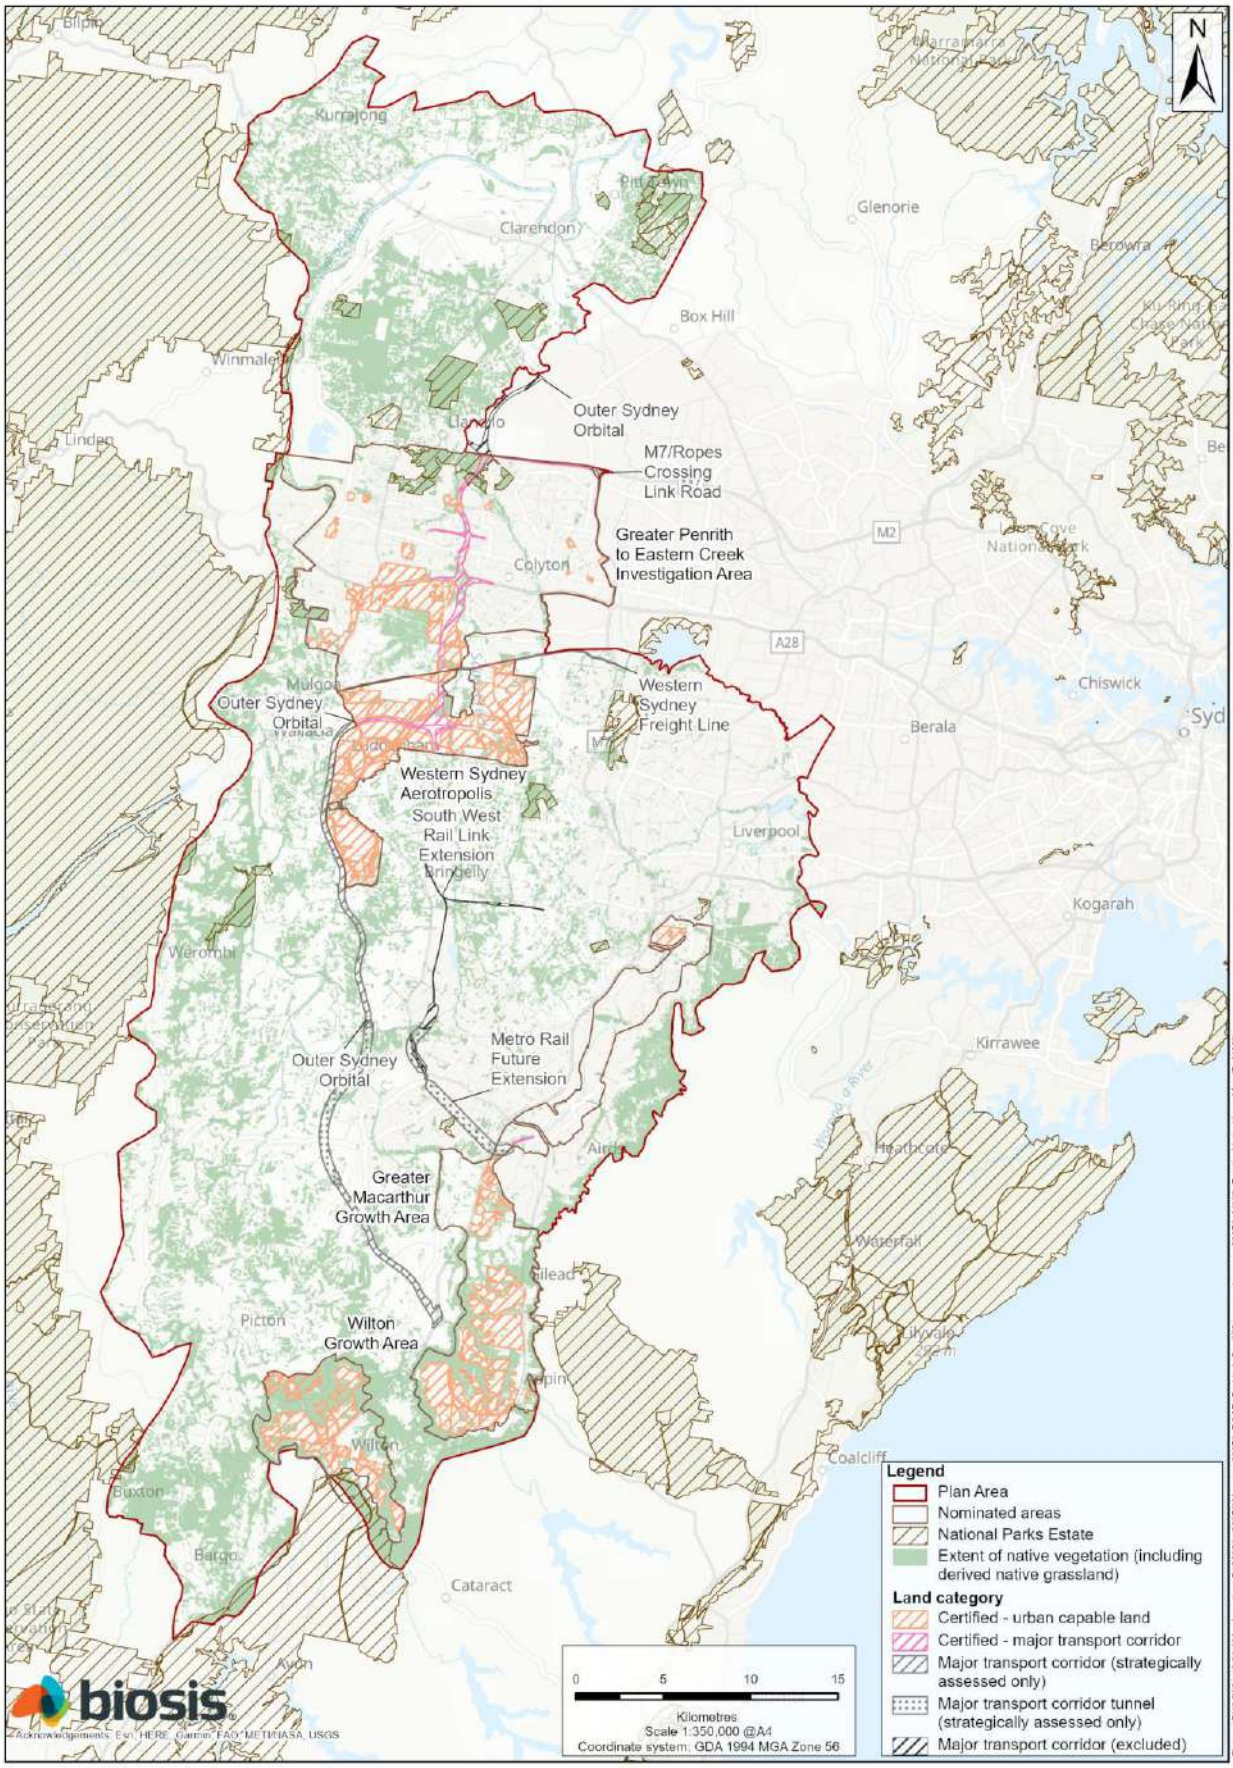

Figure 28-1: Extent of native vegetation in the Strategic Assessment Area

28.1.3 ECOLOGICAL PROCESSES

The ecological processes in an area determine the species composition, habitat structure, and ecological health of sites and landscapes. They include biological, physical, and chemical processes such as natural disturbance, hydrology, nutrient cycling, flora and fauna interactions, population dynamics, and evolution (US EPA, 1999).

There are several ecological processes that are particularly relevant to consideration of the Plan and its contribution to the Cumberland subregion. They are:

- Habitat connectivity and fragmentation
- Fire regimes
- Soil nutrient cycling
- Hydrology

HABITAT CONNECTIVITY AND FRAGMENTATION

Habitat connectivity refers to the degree of connectedness of areas of habitat. Habitat connectivity can include:

- Corridors of vegetation linking other areas of habitat
- Isolated patches of habitat that provide 'stepping stones' between other areas of habitat
- Habitat features (such as large trees with hollows) scattered within areas of non-habitat (e.g. urban land) that provide habtiat connectivity between intact areas of habitat

Habitat connectivity is important for biodiversity as it allows the linkage of habitats, species, communities, and ecological processes. In undisturbed areas connectivity is high, and as development increases, fragmentation occurs.

Larger patches of vegetation are often more diverse and less susceptible to 'edge effects.' Edge effects are an indirect impact of habitat fragmentation. New environmental conditions at edges can promote growth of invasive species and weeds which can compete with native flora and fauna. Altered conditions can also reduce the health of important habitat features such as hollow-bearing trees. Changes in connectivity can allow invasion of pest fauna specialising in edge habitats which may alter the behaviour of resident animals and make them at risk of higher levels of predation.

The Cumberland subregion is highly fragmented, and connectivity is already compromised to the point that many of the species that previously occurred there are no longer present (DECCW, 2011). However, it is still very important for species such as Koala, woodland birds, and a range of flora. Once clearing levels exceed 70 per cent of the landscape, biodiversity loss from fragmentation increases (DECCW, 2011). This threshold has been passed already in the Cumberland subregion (DECCW, 2011).

Significant conservation planning has occurred in the Cumberland subregion over the last decade which has examined habitat connectivity. Following the Cumberland Plain Recovery Plan (DECCW, 2011), EES prepared the Biodiversity Investment Opportunities Map (BIO Map) (OEH, 2015), to ensure that conservation funding within the subregion is targeted towards areas of greatest strategic benefit.

BIO Map identifies Priority Investment Areas (PIAs) where the protection and management of native vegetation is likely to maximise benefits to biodiversity within the subregion. The PIAs comprise:

- Core areas: large areas of native vegetation and habitat where management will be of greatest benefit to the conservation of biodiversity values. These areas represent the habitat in the Cumberland subregion most likely to support species persistence and interactions between species and landscape-scale ecological processes
- Regional biodiversity corridors: linear areas that link core areas and play a crucial role in maintaining connections between species populations that would otherwise be isolated and at greater risk of local extinction

BIO Map identifies a total of 87 core areas and 27 regional biodiversity corridors within the Cumberland subregion. The core areas comprise a total of 24,196.8 ha and the corridors a total of 17,927.5 ha.

Habitat connectivity within the Plan area was mapped by:

- Identifying BIO Map regional corridors and core areas (OEH, 2015). BIO Map corridors/core areas are likely to be the most important areas of habitat connectivity in the nominated areas for the majority of species. EES had only identified BIO Map corridors within the boundaries of the Cumberland subregion. To undertake the mapping for

the small parts of the nominated areas outside the Cumberland subregion the Priority Conservation Lands layer (DECCW, 2010b) or the native vegetation map (see Chapter 19) was used to extend the BIO Map corridor mapping

- Identifying local corridors using the native vegetation mapping to identify connected patches of native vegetation. This was done visually in GIS, with only contiguous patches identified as being connected
- Identify any remaining native vegetation not within a regional corridor or local corridor as:
    - Connected – within 100 m of another patch of woody vegetation
    - Isolated – greater than 100 m from another patch of woody vegetation

Key areas of habitat connectivity in the nominated areas are shown in Map 28-1.

FIRE

Fire has been shown to be important in maintaining native species richness in remnant grasslands in south-eastern Australia (Lunt & Morgan, 2002; Lunt, Prober et al., 2012).

Fire regimes in the Cumberland subregion were established over hundreds of years and fire plays an important role in shaping the landscape and vegetation. The fire regimes of the subregion have been significantly altered over time due to urbanisation. In and around urban areas, fire is primarily used to manage fire risk to property from surrounding vegetation. This results in either more frequent fires than would occur naturally (through hazard reduction burns), or alternatively the total exclusion of fire. Both situations represent a deviation from natural fire patterns, and this impacts fire-dependent vegetation communities.

Fire regimes are characterised by their frequency, seasonality, and intensity. Different ecological communities have different recommended fire intervals. For example, the suggested minimum fire interval for Cumberland Plain Woodland is five years and the maximum fire interval is 12 years (DECCW, 2011). For other communities, including Moist Shale Woodland and Western Sydney Dry Rainforest, burning is not recommended at all (DECCW, 2011). In general, grassy woodlands require a higher fire frequency than shrubby woodlands (DECCW, 2011).

Particularly relevant to restoration efforts, fire can be used to increase the native species richness in previously cleared Cumberland Plain Woodland derived grasslands (Morris, de Barse et al., 2016).

SOIL NUTRIENT CYCLING

Soil nutrient cycling is another important ecological process that contributes to the healthy functioning of vegetation communities and species habitats on the Cumberland subregion. It does this through storing water and carbon and transforming waste and nutrients.

Natural soil nutrient cycling processes have been negatively affected in several ways through urbanisation and agricultural practices. Grazing has led to soil compaction, which hinders the re-establishment of a diverse native understorey, and makes soil more susceptible to erosion.

The soils of Cumberland Plain woodland communities have been shown to be subject to nutrient loading from fertilisers from previous agricultural use, deposition of livestock dung, rubbish dumping and stormwater runoff from urban areas (NSW Scientific Committee, 2009). The soils of other vegetation communities within the Cumberland subregion would have likely also been subject to similar nutrient loading.

The effects of agriculture and urbanisation on soils of the Cumberland subregion have promoted invasion by exotic species, displacing native species (Hill, Tung et al., 2005). Areas that have been cleared and grazed are now dominated by exotics (mainly perennial grasses), which make up two thirds of the canopy cover and up to half of species richness (Hill, Tung et al., 2005). This is partly due to elevated levels of soil nitrogen (which is found in fertilisers) that creates conditions which favour that exotic species over native species.

Understanding soil nutrient cycling is relevant for restoration efforts. A study examining barriers to restoring Cumberland Plain Woodland on previously cleared areas found that adding carbon to the soil and/or fire, when combined with native seed addition, increased the abundance and species richness of native species relative to exotic species (Morrie & de Barse, 2013). Adding carbon to the soil reduces the nitrate levels in the soil and increases soil microbes, creating conditions that allow natives to be more competitive with exotic species.

HYDROLOGY

The Strategic Assessment Area occurs within two catchments and is traversed by a number of major rivers and a wide range of smaller waterways (see Figure 28-2). The two catchments are:

- Botany Bay
- Hawkesbury-Nepean

Development and agricultural practices over the years have reduced riparian vegetation and impacted the hydrology of the catchments. During heavy rain water moves more quickly off surfaces which leads to flooding, erosion, and sedimentation and can contribute to reduced water quality (DEC, 2005b). For plants and animals dependent on flood flows to trigger critical life cycle events, changes to hydrology could impact their viability.

Botany Bay catchment

Parts of Greater Macarthur Growth Area (GMAC) occur within the Georges River sub-catchment of the Botany Bay catchment. The Georges River ultimately flows directly into Botany Bay and the waters surrounding Towra Point Ramsar site (outside the Strategic Assessment Area).

The water quality of the Georges River varies depending upon the degree of development within each sub-catchment of the river. The water quality in the vicinity of GMAC ranges from poor (within the Bunbury-Curran Creek sub-catchment) to good (the Mid Georges River sub-catchment) (GRCCC, 2017). Large areas of the upper reaches of the catchment are vegetated, which provides protection from activities that reduce water quality.

Hawkesbury-Nepean catchment

The majority of the Strategic Assessment Area occurs within the Hawkesbury-Nepean catchment. The catchment is one of the longest coastal catchments in NSW, stretching from Broken Bay in the north to Goulburn in the south with the Hawkesbury-Nepean river flowing for 470 km and draining more than 22,000 km^2 of land (Western Sydney University, 2016).

The Nepean River flows south to north through the Strategic Assessment Area to near the point that it becomes the Hawkesbury River where it junctions to the Grose River. Wianamatta (South Creek) is another major waterway running through Western Sydney Aerotropolis (WSA) and Greater Penrith to Eastern Creek Investigation Area (GPEC). Many of the waterways in the Strategic Assessment Area have extensive floodplains (GES, 2018).

Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by the negative effects of historical land uses (e.g. clearing, urbanisation) (GES, 2018).

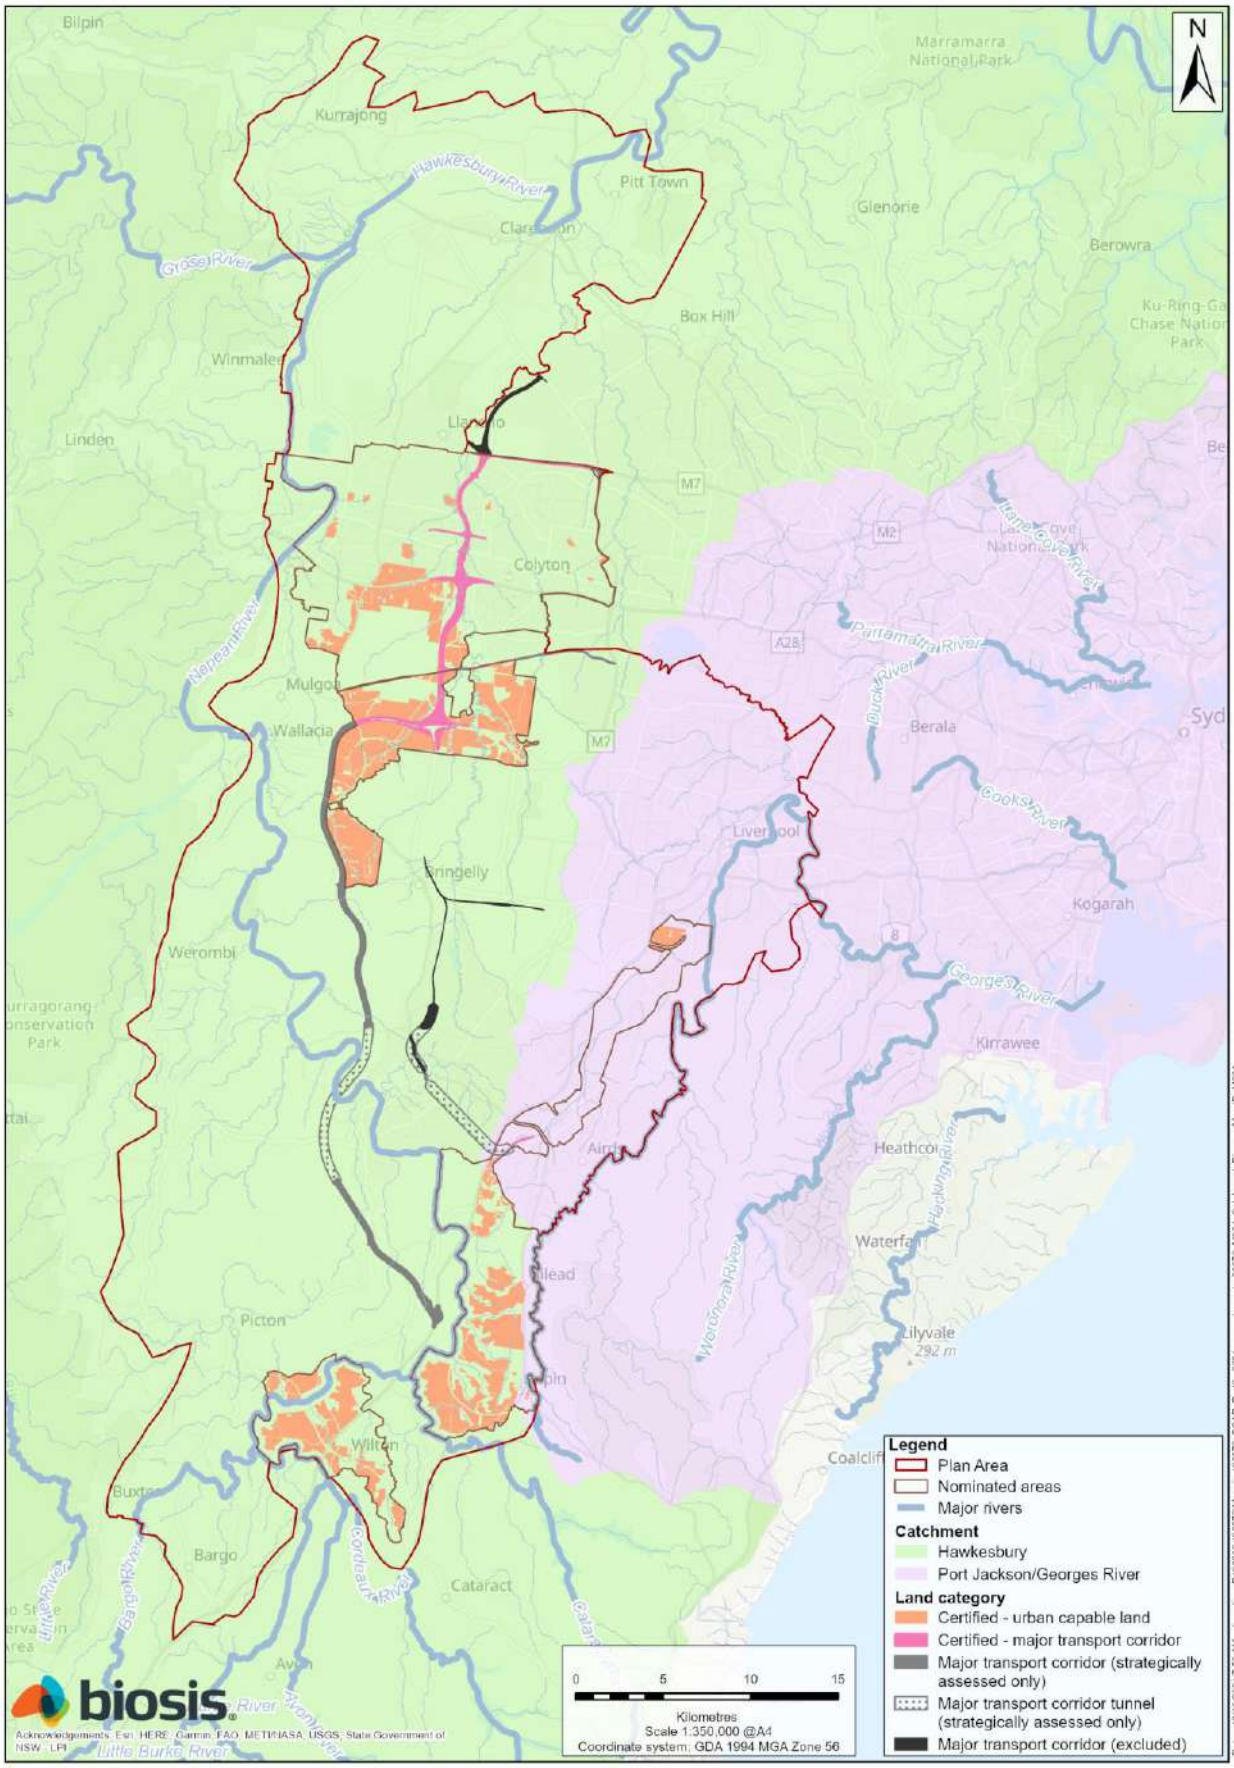

Figure 28-2: Major rivers of the Strategic Assessment Area

28.1.4 THREATENING PROCESSES

A process is defined as a threatening process under the EPBC Act if it threatens or may threaten the survival, abundance or evolutionary development of a native species or ecological community.

The EPBC Act enables the listing of key threatening processes. A threatening process may be added to the list of key threatening processes in several circumstances, including where it could cause a native species or an ecological community to become eligible for listing under the EPBC Act as threatened.

The key threatening processes in the Cumberland subregion fall into the following categories:

- Habitat loss
- Climate change
- Weeds
- Pest animals
- Fire
- Disease

HABITAT LOSS

Habitat loss is one of the key threats to the biodiversity of the Cumberland subregion (DECCW, 2011). Further clearing of native vegetation places more pressure on already over-cleared landscapes and leads to increasingly isolated and small remnants that are more susceptible to degradation, provide less habitat and support fewer species (DECCW, 2011).

The EPBC Act lists 'land clearance' under this category.

CLIMATE CHANGE

Climate change is a key threat to the biodiversity of the Cumberland subregion (DECCW, 2011). The nature and extent of the threat is difficult to quantify, but may include (DECCW, 2010a):

- Reductions in the geographic range of species
- Changes to the timing of species' lifecycle events
- Changes in population dynamics and survival
- Changes in the location of species' habitats
- Increases in the risk of extinction for species that are already vulnerable
- Increased opportunity for range expansion of invasive species
- Changes in the structure and composition of ecosystems and communities
- Increased likelihood of extreme weather events and fire
- Changes in coastal and estuarine habitat due to rising sea levels

The EPBC Act lists 'loss of climatic habitat caused by anthropogenic emissions of greenhouse gases' under this category.

WEED INVASION

Weed invasion is an ongoing threat to the remaining vegetation in the Cumberland subregion. In particular, African Olive, African Lovegrass, and Bridal Creeper have established themselves widely, are very competitive and can dominate native understory species (DECCW, 2011; Tozer, 2003).

Key threatening processes listed under the EPBC Act in this category include:

- Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants
- Novel biota and their impact on biodiversity

Several threatening processes relevant to the subregion are also listed under the *Biodiversity Conservation Act 2016* (BC Act) in this category, including:

- Invasion of native plant communities by African Olive
- Invasion, establishment and spread of Lantana
- Invasion of native plant communities by exotic perennial grasses

PEST ANIMALS

Pest animals are a key threat to native fauna species and native vegetation in the Cumberland subregion, including threatened ecological communities such as Cumberland Plain Woodland (DIPNR, 2003). Grazing by pest animals has prevented the recovery and regeneration of native species (DIPNR, 2003).

KTPs listed under the EPBC Act in this category include:

- Aggressive exclusion of birds from potential woodland and forest habitat by over-abundant noisy miners (*Manorina melanocephala*)
- Competition and land degradation by rabbits
- Competition and land degradation by unmanaged goats
- Predation by European red fox
- Predation by feral cats
- Predation, habitat degradation, competition, and disease transmission by feral pigs
- The biological effects, including lethal toxic ingestion, caused by Cane Toads (*Bufo marinus*)

FIRE

Inappropriate fire regimes are a key issue for biodiversity, particularly ecological communities, in the Cumberland subregion. Frequent fire from arson is a major problem and has resulted in a significant change to ecological communities in the subregion, which have evolved and been selected by pre-European practices to be dependent on a certain fire regime (DECCW, 2011).

High frequency fire and inappropriate fire regimes have been identified as threats to a number of species and ecological communities in the Cumberland subregion, including Cumberland Plain Woodland (NSW Scientific Committee, 2000).

No key threatening processes listed under the EPBC Act are included in this category.
